Background of Invention

FIELD OF THE INVENTION

[0004] The present invention relates to a group of bioinformatically detectable novel genes, here identified as "genomic address messenger"or "GAM"genes, which are believed to be related to the micro RNA (miRNA) group of genes.

Description of Prior Art

[0005] Over 300 small noncoding RNA"s, termed Micro RNA"s (miRNA"s), have been identified to date in animals and plants (1-8). The MIR genes, code for ~70-120nt long non-protein-coding RNA sequences, that are the precursors of the ~22 nt miRNA sequences, which in some cases, specifically inhibit translation of target genes, by complementary binding to their untranslated regions (UTR) (9-13). The first two MIR genes discovered, Lin-4 and Let-7, were found in the nematode Ceanorhabditis elegans, and shown to be involved in developmental timing (14, 15), hence originally called Short Temporal RNA (stRNA) (16). The ~22 nt sequences inhibit translation of two respective target genes, Lin-14 and Lin-41, by complementary binding to their 3" untranslated regions (UTR) (14, 17). Later studies by three separate groups (1-3) identified several precursor and mature miRNA"s, some of them in clusters (1), expressed as sequences found in size fractionated (<80nt) total RNA, in a wide spectrum of species, including C. elegans, Drosophila melanogaster, Homo sapiens, as well as plants. More recently, additional miRNA"s from human (mir-91 to mir-121 (6)), mouse (mir-122 to mir-155 (4)) and plants (mir-156 to mir-171 (5)), have been reported. Furthermore, Llave et al identi-

fied in Arabidopsis thaliana 125 sequences, 21-24 nucleotides in length and presumably miRNAs (8). Each of the MIR genes is transcribed and processed to an ~80 nt-long hairpin shaped miRNA precursor, which is then processed by an enzyme called Dicer, to yield the mature ~22 nt-long single stranded miRNA. Such small RNAs will inhibit translation of target genes by complementary binding to sites in the 3" or 5" untranslated regions (18). Their structural similarity to the two well-studied miRNA"s in C. elegans, Lin-4 and Let-7, supports the belief that MIR genes code for specific translation inhibitors of target genes. However, determining the targets of the miRNAs is more complicated than just searching for antisense complementarity, because bulges and loops, disrupting perfect complementarity, are not only tolerated, but seem to be the rule in the postulated binding between the miRNA"s and their target UTR"s(19). Target-gene binding sites of most reported miRNA"s, except of Lin-4 and Let-7, have not been found, and therefore the specific functionality of these genes is still unknown. Using a computational approach, Rhoades et al (19), predicted targets for 14 A. thaliana miRNA"s by identifying their near complementarity to the predicted targets. However, using the

same approach was not helpful in identifying miRNA targets in C. elegans and D. melanogaster, raising the possibility that the near-perfect complementarity appears to be specific to plants (19).

[0006] The ability to detect novel RNA genes is limited by the methodologies used to detect such genes. All RNA genes identified so far either present a visibly discernable whole body phenotype, as do Lin-4 and Let-7 (Wightman et. al., Cell 75, 855 (1993); Reinhart et al., Nature 403, 901 (2000)), or produce significant enough quantities of RNA so as to be detected by the standard biochemical genomic techniques, as do the 93 recently detected miRNA genes. Since a limited number clones were sequenced by the researchers discovering these genes, 300 by Bartel and 100 by Tuschl (Bartel et. al., Science 294 ,858 (2001); Tuschl et. al., Science 294 ,853 (2001)), the RNA genes found can not be much rarer than 1% of all RNA genes. The recently detected miRNA genes therefore represent the more prevalent among the miRNA gene family.

[0007] Current methodology has therefore been unable to detect RNA genes which either do not present a visually discernable whole body phenotype, or are rare (e.g. rarer than 0.1% of all RNA genes), and therefore do not produce sig-

nificant enough quantities of RNA so as to be detected by standard biochemical technique.

SUMMARY OF INVENTION

[0008] The present invention relates to a novel group of regulatory, non-protein coding genes, which are functional in specifically inhibiting translation of other genes, some of which are known to be involved in various diseases. Each gene in this novel group of genes, here identified as "GAM"or "Genomic Address Messengers", specifically inhibits translation of one of more other "target" genes by means of complimentary hybridization of a segment of the RNA transcript encoded by GAM2, to an inhibitor site located in the 3"untranslated region of the mRNA of the one or more "target" genes.

[0009] In various preferred embodiments, the present invention seeks to provide improved method and system for specific modulation of expression of specific known "target" genes involved in significant human diseases, and improved method and system for detection of expression of these target genes.

[0010] Accordingly, the invention provides several substantially pure DNAs (e.g., genomic DNA, cDNA or synthetic DNA) each encoding a novel gene of the GAM group of gene,

vectors comprising the DNAs, probes comprising the DNAs, a method and system for selectively modulating translation of known "target" genes utilizing the vectors, and a method and system for detecting expression of known "target" genes utilizing the probe.

[0011] By "substantially pure DNA" is meant DNA that is free of the genes which, in the naturally-occurring genome of the organism from which the DNA of the invention is derived, flank the genes discovered and isolated by the present invention. The term therefore includes, for example, a recombinant DNA which is incorporated into a vector, into an autonomously replicating plasmid or virus, or into the genomic DNA of a prokaryote or eukaryote at a site other than its natural site; or which exists as a separate molecule (e.g., a cDNA or a genomic or cDNA fragment produced by PCR or restriction endonuclease digestion) independent of other sequences. It also includes a recombinant DNA which is part of a hybrid gene encoding additional polypeptide sequence.

[0012] "Inhibiting translation" is defined as the ability to prevent synthesis of a specific protein encoded by a respective gene, by means of inhibiting the translation of the mRNA of this gene. "Translation inhibiter site" is defined as the

minimal DNA sequence sufficient to inhibit translation.

[0013] There is thus provided in accordance with a preferred embodiment of the present invention a bioinformatically detectable novel gene encoding substantially pure DNA wherein: RNA encoded by the bioinformatically detectable novel gene is about 18 to about 24 nucleotides in length, and originates from an RNA precursor, which RNA precursor is about 50 to about 120 nucleotides in length, a nucleotide sequence of a first half of the RNA precursor is a partial inversed-reversed sequence of a nucleotide sequence of a second half thereof, a nucleotide sequence of the RNA encoded by the novel gene is a partial inversed-reversed sequence of a nucleotide sequence of a binding site associated with at least one target gene, the novel gene cannot be detected by either of the following: a visually discernable whole body phenotype, and detection of 99.9% of RNA species shorter than 25 nucleotides expressed in a tissue sample, and a function of the novel gene is bioinformatically deducible.

[0014] There is further provided in accordance with another preferred embodiment of the present invention a bioinformatically detectable novel gene encoding substantially pure DNA wherein: RNA encoded by the bioninformatically

detectable novel gene includes a plurality of RNA sections, each of the RNA sections being about 50 to about 120 nucleotides in length, and including an RNA segment, which RNA segment is about 18 to about 24 nucleotides in length, a nucleotide sequence of a first half of each of the RNA sections encoded by the novel gene is a partial inversed-reversed sequence of nucleotide sequence of a second half thereof, a nucleotide sequence of each of the RNA segments encoded by the novel gene is a partial inversed-reversed sequence of the nucleotide sequence of a binding site associated with at least one target gene, and a function of the novel gene is bioinformatically deducible from the following data elements: the nucleotide sequence of the RNA encoded by the novel gene, a nucleotide sequence of the at least one target gene, and function of the at least one target gene.

[0015] There is still further provided in accordance with another preferred embodiment of the present invention a bioinformatically detectable novel gene encoding substantially pure DNA wherein: RNA encoded by the bioinformatically detectable novel gene is about 18 to about 24 nucleotides in length, and originates from an RNA precursor, which RNA precursor is about 50 to about 120 nucleotides in

length, a nucleotide sequence of a first half of the RNA precursor is a partial inversed-reversed sequence of a nucleotide sequence of a second half thereof, a nucleotide sequence of the RNA encoded by the novel gene is a partial inversed-reversed sequence of a nucleotide sequence of a binding site associated with at least one target gene, a function of the novel gene is modulation of expression of the at least one target gene, and the at least one target gene does not encode a protein.

[0016] There is additionally provided in accordance with another preferred embodiment of the present invention A bioinformatically detectable novel gene encoding substantially pure DNA wherein: the bioinformatically detectable novel gene does not encode a protein, RNA encoded by the bioinformatically detectable novel gene is maternally transferred by a cell to at least one daughter cell of the cell, a function of the novel gene includes modulation of a cell type of the daughter cell, and the modulation is bioinformatically deducible.

[0017] There is moreover provided in accordance with another preferred embodiment of the present invention a bioinformatically detectable novel gene encoding substantially pure DNA wherein: the bioinformatically detectable novel

gene does not encode a protein, a function of the novel gene is promotion of expression of the at lease one target gene, and the at least one target gene is bioinformatically deducible.

[0018] Further in accordance with a preferred embodiment of the present invention the function of the novel gene is bioinformatically deducible from the following data elements: the nucleotide sequence of the RNA encoded by the bioinformatically detectable novel gene, a nucleotide sequence of the at least one target gene, and a function of the at least one target gene.

[0019] Still further in accordance with a preferred embodiment of the present invention the RNA encoded by the novel gene complementarily binds the binding site associated with the at least one target gene, thereby modulating expression of the at least one target gene.

[0020] Additionally in accordance with a preferred embodiment of the present invention the binding site associated with at least one target gene is located in an untranslated region of RNA encoded by the at least one target gene.

[0021] Moreover in accordance with a preferred embodiment of the present invention the function of the novel gene is selective inhibition of translation of the at least one target

gene, which selective inhibition includes complementary hybridization of the RNA encoded by the novel gene to the binding site.

[0022] Further in accordance with a preferred embodiment of the present invention the invention includes a vector including the DNA.

[0023] Still further in accordance with a preferred embodiment of the present invention the invention includes a method of selectively inhibiting translation of at least one gene, including introducing the vector.

[0024] Moreover in accordance with a preferred embodiment of the present invention the introducing includes utilizing RNAi pathway.

[0025] Additionally in accordance with a preferred embodiment of the present invention the invention includes a gene expression inhibition system including: the vector, and a vector inserter, functional to insert the vector into a cell, thereby selectively inhibiting translation of at least one gene.

[0026] Further in accordance with a preferred embodiment of the present invention the invention includes a probe including the DNA.

[0027] Still further in accordance with a preferred embodiment of

the present invention the invention includes a method of selectively detecting expression of at least one gene, including using the probe.

[0028] Additionally in accordance with a preferred embodiment of the present invention the invention includes a gene expression detection system including: the probe, and a gene expression detector functional to selectively detect expression of at least one gene.

Brief Description of Drawings

specific genes of a second group of novel genes of the present invention, detected using the bioinformatic gene detection system described hereinabove with reference to Figs. 8 through 15.

Brief Description of Sequences

[0053] A Sequence Listing of genomic sequences of the present invention is attached to this application, enclosed in computer readable form.

Detailed Description

[0054] Reference is now made to Fig. 1 which is a simplified diagram providing a conceptual explanation of a genomic differentiation enigma, which the present invention addresses.

[0055] Referring to Fig. 1, it is appreciated that different cell types in an organism, such as CARTILAGE CELL, LIVER CELL, FIBROBLAST CELL and BONE CELL all contain identical DNA, and derive from the initial FERTILIZED EGG CELL, and yet each of these cells expresses different proteins, and hence acquires different shape and function.

[0056] The present invention proposes that the inevitable conclusion from this constraint is, however, strikingly simple: the coding system used must be modular. It must com-

prise multiple modules, or records, one for each cell-type, and a mechanism whereby each cell at its inception is instructed which record to open, and behaves according to instructions in that record.

[0057] This modular code concept is somewhat difficult to grasp, since we are strongly habituated to viewing things from an external viewpoint. An architect, for example, looks at a blueprint of a building, which details exactly where each element (block, window, door, electrical switch, etc.) is to be placed relative to all other elements, and then instructs builders to place these elements in their designated places. This is an external viewpoint: the architect is external to the blueprint, which itself is external to the physical building, and its different elements. The architect may therefore act as an "external organizing agent": seeing the full picture and the relationships between all elements, and being able to instruct from the outside where to place each of them.

[0058] Genomics differentiation coding evidently works differently, without any such external organizing agent: It comprises only one smart block (the first cell), which is the architect and the blueprint, and which continuously duplicates itself, somehow knowing when to manifest itself as

a block and when as a window, door, or electrical switch.

[0059] Reference is now made to Figs. 2 through 4 which are schematic diagrams which when taken together provide an analogy that illustrates a conceptual model of the present invention, addressing the genomic differentiation enigma.

[0060] Referring to Fig. 2A, imagine a very talented chef, capable of preparing any meal provided he is given specific written cooking instructions. This chef is equipped with two items: (a) a thick recipe book, and (b) a small note with a number scribbled on it. The book comprises multiple pages, each page detailing how to prepare a specific meal. The small note indicates the page to be opened, and therefore the meal to be prepared. The chef looks at the page-number written on the note, opens the recipe book at the appropriate page, and prepares the meal according to the written instructions on this page. As an example, Fig. 2A depicts a CHEF holding a note with the number 12 written on it, he opens the book on page 12, and since that page contains the recipe for preparing BREAD, the CHEF prepares a loaf of BREAD.

[0061] Referring now to Fig. 2B, which depicts two identical chefs, CHEF A and CHEF B, holding an identical recipe

book. Despite their identity, and the identity of their recipe book, since CHEF A holds a note numbered 12, and therefore opens the book on page 12 and prepares BREAD, whereas CHEF B holds a note numbered 34 and therefore opens the book on page 34 and prepares a PIE.

[0062] Referring now to Fig. 3. Imagine the chef of the analogy is also capable of duplicating himself once he has finished preparing the specified meal. The format of the book is such that at the bottom of each page, two numbers are written. When he has finished preparing the meal specified on that page, the chef is trained to do the following: (i) divide himself into two identical duplicate chefs, (ii) duplicate the recipe book and hand a copy to each of his duplicate chefs, and (iii) write down the two numbers found at the bottom of the page of the meal he prepared, on two small notes, handing one note to each of his two duplicate chefs.

[0063] Each of the two resulting duplicate chefs are now equipped with the same book, and have the same talent to prepare any meal, but since each of them received a different note, they will now prepare different meals.

[0064] Fig. 3 depicts CHEF A holding a recipe book and receiving a note numbered 12. CHEF A therefore opens the book on

page 12 and prepares BREAD. When he is finished making bread, CHEF A performs the following actions: (i) divides himself into two duplicate chefs, designated CHEF B and CHEF C, (ii) duplicates his recipe book handing a copy to each of CHEF B and CHEF C, (iii) writes down the numbers found at the bottom of page 12, numbers 34 and 57, on two notes, handing note numbered 34 to CHEF B and note numbered 57 to CHEF C.

[0065] Accordingly, CHEF B receives a note numbered 34 and therefore opens the recipe book on page 34 and prepares PIE, whereas CHEF C receives a note numbered 57 and therefore opens the book on page 57 and therefore prepares RICE.

[0066] It is appreciated that while CHEF A, CHEF B & CHEF C are identical and hold identical recipe books, they each prepare a different meal. It is also appreciated that the meals prepared by CHEF B and CHEF C are determined CHEF A, and are mediated by the differently numbered notes passed on from CHEF A to CHEF B and CHEF C.

[0067] It is further appreciated that the mechanism illustrated by Fig. 3 enables an unlimited lineage of chefs to divide into duplicate, identical chefs and to determine the meals those duplicate chefs would prepare. For example, having

been directed to page 34, when CHEF B divides into duplicate chefs (not shown), he will instruct its two duplicate chefs to prepare meals specified on pages 14 and 93 respectively, according to the numbers at the bottom of page 34 to which he was directed. Similarly, CHEF C will instruct its duplicate chefs to prepare meals specified on pages 21 and 46 respectively, etc.

[0068] Referring now to Fig. 4. Imagine that the cooking instructions on each page of the recipe book are written in shorthand format: The main meal-page to which the chef was directed by the scribbled note, merely contains a list of numbers which direct him to multiple successive pages, each specifying how to prepare an ingredient of that meal.

[0069] As an example, Fig. 4 depicts CHEF A of FIGS 2 and 3, holding a recipe book and a note numbered 12. Accordingly, CHEF A opens the recipe book on page 12, which details the instructions for preparing BREAD. However, the "instructions" on making BREAD found on page 12 comprise only of 3 numbers, 18, 7 and 83, which "refer" CHEF A to pages detailing preparation of the ingredients of BREAD FLOUR, MILK and SALT, respectively.

[0070] As illustrated in Fig. 4, turning from the main "meal page" (e.g. 12) to respective "ingredients pages" (e.g. pages 18,

7 & 83) is mediated by scribbled notes with the page-numbers written on them. In this analogy, the scribbled notes are required for seeking the target pages to be turned to both when turning to main "meal pages" (e.g. page 12), as well as when turning to "ingredient pages" (e.g. pages 18, 7 & 83).

[0071] The chef in the given analogy, schematically depicted in FIGS 2 through 4, represents a cell; the thick recipe book represents the DNA; preparing a meal in the given analogy represents the cell manifesting itself as a specific cell-type; and ingredients of a meal represent proteins expressed by that cell-type. Like the chef equipped with the thick recipe book in the given analogy, all cells in an organism contain the same DNA and are therefore each potentially capable of manifesting itself as any cell-type, expressing proteins typical of that cell type.

[0072] Reference is now made to Figs. 5A and 5B which are schematic diagrams, which when taken together illustrate a "genomic records" concept of the conceptual model of the present invention, addressing the genomic differentiation enigma.

[0073] The Genomic Records concept asserts that the DNA (the thick recipe book in the illustration) comprises a very

large number of Genomic Records (analogous to pages in the recipe book), each containing the instructions for differentiation of a different cell-type, or developmental process. Each Genomic Record is headed by a very short genomic sequence which functions as a "Genomic Address" of that Genomic Record (analogous to the page number in the recipe book). At its inception, in addition to the DNA, each cell also receives a short RNA segment (the scribbled note in the illustration). This short RNA segment binds complementarily to a "Genomic Address" sequence of one of the Genomic Records, thereby activating that Genomic Record, and accordingly determining the cell"s-fate (analogous to opening the book on the page corresponding to the number on the scribbled note, thereby determining the meal to be prepared).

[0074] Referring to Fig. 5A, a CELL is illustrated which comprises a GENOME. The GENOME comprises a plurality of GENOMIC RECORDS, each of which correlates to a specific cell type (for clarity only 6 sample genomic records are shown). Each genomic record comprises genomic instructions on differentiation into a specific cell-type, as further elaborated below with reference to Fig. 7. At cell inception, the CELL receives a maternal short RNA segment,

which activates one of the GENOMIC RECORDS, causing the cell to differentiate according to the instructions comprised in that genomic record. As an example, Fig. 5A illustrates reception of a maternal short RNA segment designated A" and outlined by a broken line, which activates the FIBRO genomic record, causing the cell to differentiate into a FIBROBLAST CELL.

[0075] Referring now to Fig. 5B, which is a simplified schematic diagram, illustrating cellular differentiation mediated by the "Genomic Records" concept. Fig. 5B depicts 2 cells in an organism, designated CELL A and CELL B, each having a GENOME. It is appreciated that since CELL A and CELL B are cells in the same organism, the GENOME of CELL A is identical to that of CELL B. Despite having an identical GENOME, CELL A differentiates differently from CELL B, due to activation of different genomic records in these two cells. In CELL A the FIBRO GENOMIC RECORD is activated, causing CELL A to differentiate into a FIBROBLAST CELL, whereas in CELL B the BONE GENOMIC RECORD is activated, causing the CELL B to differentiate into a BONE CELL. The cause for activation of different genomic records in these two cells is the different maternal short RNA which they both received: CELL A received a maternal

short RNA segment designated A" which activated genomic record FIBRO, whereas CELL B received a maternal short RNA segment designated B" which activated genomic record BONE.

[0076] Reference is now made to Fig. 6 which is a schematic diagram illustrating a "genomically programmed cell differentiation" concept of the conceptual model of the present invention, addressing the genomic differentiation enigma.

[0077] A cell designated CELL A divides into 2 cells designated CELL B and CELL C. CELL A, CELL B and CELL C each comprise a GENOME, which GENOME comprises a plurality of GENOMIC RECORDS. It is appreciated that since CELL A, CELL B and CELL C are cells in the same organism, the GENOME of these cells, and the GENOMIC RECORDS comprised therein, are identical.

[0078] As described above with reference to Fig. 5B, at its inception, CELL A receives a maternal short RNA segment, designated A" and marked by a broken line, which activates the FIBRO genomic record, thereby causing CELL A to differentiate into a FIBROBLAST CELL. However, Fig. 6 shows further details of the genomic records: each cell genomic record also comprises two short genomic sequences, referred to here as Daughter Cell Genomic Addresses.

Blocks designated B and C are Daughter Cell Genomic Addresses of the FIBRO Genomic Record. At cell division, each parent cell transcribes two short RNA segments, corresponding to the two Daughter Cell Genomic Addresses of the Genomic Record of that parent cell, and transfers one to each of its two daughter cells. CELL A of Fig. 6 transcribes and transfers to its two respective daughter cells, two short RNA segments, outlined by a broken line and designated B" and C", corresponding to daughter cell genomic addresses designated B and C comprised in the FIBRO genomic record.

[0079] CELL B therefore receives the above mentioned maternal short RNA segment designated B", which binds complementarily to genomic address designated B of genomic record BONE, thereby activating this genomic record, which in turn causes CELL B to differentiate into a BONE CELL. Similarly, CELL C receives the above mentioned maternal short RNA segment designated C", which binds complementarily to genomic address designated C of genomic record CARTIL., thereby activating this genomic record, which in turn causes CELL C to differentiate into a CARTILAGE CELL.

[0080] It is appreciated that the mechanism illustrated by Fig. 6

enables an unlimited lineage of cells to divide into daughter cells containing the same DNA, and to determine the cell-fate of these daughter cells. For example, when CELL B and CELL C divide into their respective daughter cells (not shown), they will transfer short RNA segments designated D" & E", and F" & G" respectively, to their respective daughter cells. The cell fate of each of these daughter cells would be determined by the identity of the maternal short RNA segment they receive, which would determine the genomic record activated.

[0081] Reference is now made to Fig. 7 which is a schematic diagram illustrating a "genomically programmed cell-specific protein expression modulation" concept of the conceptual model of the present invention, addressing the genomic differentiation enigma.

[0082] Cell A receives a maternal short RNA segment designated A", which activates a genomic record designated FIBRO, by anti-sense binding to a binding site "header" of this genomic record, designated A. Genomic record FIBRO encodes 3 short RNA segments, designated 1, 2 and 4 respectively, which modulate expression of target genes designated GENE1, GENE2 and GENE4 respectively. Modulation of expression of these genes results in CELL A dif-

ferentiating into a FIBROBLAST CELL.

[0083] Reference is now made to Fig. 8 which is a simplified diagram illustrating a mode by which genes of a novel group of genes of the present invention, modulate expression of known target genes.

[0084] The novel genes of the present invention are micro RNA (miRNA)-like, regulatory RNA genes, modulating expression of known target genes. This mode of modulation is common to other known miRNA genes, as described hereinabove with reference to the background of the invention section.

[0085] GAM GENE and TARGET GENE are two human genes contained in the DNA of the human genome.

[0086] GAM GENE encodes a GAM PRECURSOR RNA. However, similar to other miRNA genes, and unlike most ordinary genes, its RNA, GAM PRECURSOR RNA, does not encode a protein.

[0087] GAM PRECURSOR RNA folds onto itself, forming GAM FOLDED PRECURSOR RNA. As Fig.8 illustrates, GAM FOLDED PRECURSOR RNA forms a "hairpin structure", folding onto itself. As is well known in the art, this "hairpin structure", is typical genes of the miRNA genes, and is due to the fact that nucleotide sequence of the first half of

the RNA of a gene in this group is an accurate or partial inversed-reversed sequence of the nucleotide sequence of its second half. By "inversed-reversed"is meant a sequence which is reversed and wherein each nucleotide is replaced by a complimentary nucleotide, as is well known in the art (e.g. ATGGC is the inversed-reversed sequence of GCCAT).

[0088] An enzyme complex, designated DICER COMPLEX, "dices" the GAM FOLDED PRECURSOR RNA into a single stranded RNA segment, about 22 nucleotides long, designated GAM RNA. As is known in the art, "dicing" of the hairpin structured RNA precursor into shorter RNA segments about 22 nucleotides long by a Dicer type enzyme is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins.

[0089] TARGET GENE encodes a corresponding messenger RNA, designated TARGET RNA. This TARGET RNA comprises 3 regions: a 5" untranslated region, a protein coding region and a 3" untranslated region, designated 5"UTR, PROTEIN CODING and 3"UTR respectively.

[0090] GAM RNA binds complimentarily a BINDING SITE, located on the 3"UTR segment of TARGET RNA. This complimentarily binding is due to the fact that the nucleotide se-

quence of GAM RNA is an accurate or partial inversed-reversed sequence of the nucleotide sequence of BINDING SITE.

[0091] The complimentary binding of GAM RNA to BINDING SITE inhibits translation of TARGET RNA into TARGET PROTEIN. TARGET PROTEIN is therefore outlined by a broken line.

[0092] It is appreciated by one skilled in the art that the mode of transcriptional inhibition illustrated by Fig. 1 with specific reference to GAM genes of the present invention, is in fact common to all other miRNA genes. A specific complimentary binding site has been demonstrated only for Lin-4 and Let-7. All the other 93 newly discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complimentary binding, although specific complimentary binding sites for these genes have not yet been found (Ruvkun G., "Perspective: Glimpses of a tiny RNA world", Science 294 ,779 (2001)). The present invention discloses a novel group of genes, the GAM genes, belonging to the miRNA genes group, and for which a specific an complimentary binding has been determined.

[0093] Reference is now made to Fig. 9 which is a simplified block diagram illustrating a bioinformatic gene detection

system capable of detecting genes of the novel group of genes of the present invention, which system is constructed and operative in accordance with a preferred embodiment of the present invention.

[0094] A bioinformatic gene detection engine 100, is a preferred implementation of a mechanism capable of detecting genes of the novel group of genes of the present invention.

[0095] The function of the bioinformatic gene detection engine 100 is as follows: it receives three types of input, expressed RNA data 102, sequenced DNA data 104, and protein function data 106, performs a complex process of analysis of this data as elaborated below, and based on this analysis produces output of a bioinformatically detected group of novel genes designated 108.

[0096] Expressed RNA data 102 comprises published expressed sequence tags (EST) data, , published mRNA data, as well as other sources of published RNA data. Sequenced DNA data 104 comprises alphanumeric data describing sequenced genomic data, which preferably includes annotation data such as location of known protein coding regions relative to the sequenced data. Protein function data 106 comprises scientific publications reporting studies

which elucidated physiological function known proteins, and their connection, involvement and possible utility in treatment and diagnosis of various diseases. Expressed RNA data 102, sequenced DNA data 104 may preferably be obtained from data published by the National Center for Bioinformatics (NCBI) at the National Institute of Health (NIH), as well as from various other published data sources. Protein function data 106 may preferably be obtained from any one of numerous relevant published data sources, such as the Online Mendelian Inherited Disease In Man (OMIM) database developed by John Hopkins University, and also published by NCBI.

[0097] Prior to actual detection of bioinformatically detected novel genes 108 by the bioinformatic gene detection engine 100, a process of bioinformatic gene detection engine training & validation designated 110 takes place. This process uses the known miRNA genes as a training set (some 200 such genes have been found to date using biological laboratory means), to train the bioinformatic gene detection engine 100 to bioinformatically recognize miRNA-like genes, and their respective potential target binding sites. Bioinformatic gene detection engine training & validation 110 is further describe hereinbelow with ref-

erence to Fig. 10.

[0098] The bioinformatic gene detection engine 100 comprises several modules which are preferably activated sequentially, and are described as follows:A non-coding genomic sequence detector 112 operative to screen for and identify non-protein coding genomic sequences. The non-coding genomic sequence detector 112 is further described hereinbelow with reference to Figs. 11A and 11B.

[0099] A hairpin detector 114 operative to locate genomic "hairpin-shaped" sequences, similar to GAM FOLDED PRECURSOR of Fig. 8. The hairpin detector 114 is further described hereinbelow with reference to Figs. 12A and 12B.

[0100] A dicer-cut location detector 116 operative to detect the location on a hairpin shaped sequence which is enzymatically cut by DICER COMPLEX of Fig. 8. The dicer-cut location detector 116 is further described hereinbelow with reference to Fig. 13A.

[0101] A target-gene binding-site detector 118 operative to detect In these ESTs, the system locates "hairpin-shaped" (i.e. hairpin) sequences, which resemble known miRNA sequences. RNA 2D folding is calculated based on free-energy, using the Zucker algorithm (used throughout the process) [reference]. The 2D structure is then evaluated to

locate hairpin structures, and meticulously compared to that of known miRNA genes.

[0102] A combined neural and Bayesian networks system is used to detect location in which the Dicer enzyme-complex is predicted to cut the final novel miRNA gene from the hairpin shaped gene-precursor. Nucleotide sequence, and "Bulges" (i.e. mismatches) on the hairpin shaped precursor, are represented as the input and output layers of several neural networks, and hidden layer/s are designed for these neural networks accordingly. The networks are trained, evaluated and validated based on the "training set" of 120 known miRNA genes, using accepted neural networks methodology; prediction is further optimized by integrating results of multiple networks [reference].

[0103] Potential target-gene binding-sites are detected, by comparison of the final-gene sequence, calculated above, to untranslated regions of known genes, followed by a comparison of the 2D structure and free-energy of the binding site to that of known miRNA binding sites.

[0104] Lastly, biological and clinical function of target genes, utilizing reference databases such as Johns Hopkins" OMIM [reference] is manually reviewed, and is compared to tissue-data of EST in which novel gene was detected.

[0105] Referring to Fig. 9, the following is a technical description of the computer hardware configuration which was used:Hardware and Software SetupComputing power presented a major challenge. Initial time estimates indicated that over 30 months (!) of computing time would be required to detect all miRNA genes in human EST data, and their respective binding sites, using a powerful 8-processor machine.

[0106] In order to address this challenge at reasonable cost, a system has been built which, comprises a cluster of one hundred PCs (Pentium IV, 1.7GHz, with 40GB storage each), connected by Ethernet to 4 servers (2-CPU, Xeon 2.2GHz, with 200GB storage each), combined with an 8-processor server (8-CPU, Xeon 550Mhz w/ 8GB RAM) connected via 2 HBA fiber-channels to an EMC Clariion 100-disks, 3.6 Terabyte storage device. Figure 2 provides an overview of this hardware configuration.

[0107] Using this configuration, a database comprising 30 billion records was created, using Microsoft"s SQL-Server database software, demonstrating remarkable performance results, including bulk insert of 1 million records in 0.8 seconds. To the best of our knowledge, this is the largest number-of-records database ever built on an In-

tel-machine, achieving unprecedented record-insert performance. The system has further been optimized such that all one hundred PCs run at 100% CPU usage continually. Using this configuration reduced the calculation time from 30 months to 20 days.

[0108] Reference is now made to Fig. 10 which is a simplified flowchart illustrating operation of a mechanism for training of a computer system to recognize the novel genes of the present invention. This mechanism is a preferred implementation of the bioinformatic gene detection engine training & validation 110 described hereinabove with reference to Fig. 9.

[0109] Reference is now made to Fig. 11A which is a simplified block diagram of a preferred implementation of the non-coding genomic sequence detector 112 described hereinabove with reference to Fig. 9.

[0110] *The system uses as input published genomic data, including expressed RNA data (EST data and mRNA data), sequenced DNA data, and protein function data, from NCBI. EST data is blast-compared [reference] to known protein coding sequences; only non-protein-coding ESTs are searched for novel RNA genes.* Reference is now made to Fig. 11B which is a simplified flowchart illustrating a preferred operation of the non-coding ge-

nomic sequence detector 112 of Fig. 9.

[0111] Reference is now made to Fig. 12A which is a simplified block diagram of a preferred implementation of the hairpin detector 114 described hereinabove with reference to Fig. 9.

[0112] Reference is now made to Fig. 12B which is a simplified flowchart illustrating a preferred operation of the hairpin detector 114 of Fig. 9.

[0113] Reference is now made to Fig. 13A which is a simplified block diagram of a preferred implementation of the dicer-cut location detector 116 described hereinabove with reference to Fig. 9.

[0114] Reference is now made to Fig. 13 B which is a simplified flowchart illustrating a preferred implementation of dicer-cut location detector training & validation 126 of Fig. 10.

[0115] Reference is now made to Fig. 14A which is a simplified block diagram of a preferred implementation of the target-gene binding-site detector 118 described hereinabove with reference to Fig. 9.

[0116] Reference is now made to Fig. 14B which is a simplified flowchart illustrating a preferred operation of the target-gene binding-site detector 118 of Fig. 9.

[0117] Reference is now made to Fig. 15 which is a simplified

flowchart illustrating a preferred operation of the function & utility analyzer 120 described hereinabove with reference to Fig. 9.

[0118] Reference is now made to Fig. 16 which is an annotated sequence of an EST comprising a novel gene detected by the gene detection system of the present invention. Fig. 16 shows the nucleotide sequence of a known human non-protein coding EST (Expressed Sequence Tag), identified as EST72223. It is appreciated that the sequence of this EST comprises sequences of one known miRNA gene, identified as MIR98, and of one novel GAM gene, referred to here as GAM-4, detected by the bioinformatic gene detection system of the present invention, described hereinabove with reference to Fig. 9.

[0119] Reference is now made to Figs. 17A and 17B that are pictures of laboratory results, which when taken together demonstrate laboratory confirmation of expression of the bioinformatically detected novel gene of Fig. 16.

[0120] Referring to Fig. 17A which is a Northern blot analysis of MIR-98 and EST72223 transcripts. MIR-98 and EST72223 were reacted with MIR-98 and GAM-4 probes as indicated in the figure. It is appreciated that the probes of both MIR-98 and GAM-4 reacted with EST72223, indicating

that EST72223 contains the sequences of MIR-98 and of GAM-4. It is further appreciated that the probe of GAM-4 did not cross-react with MIR-98.

[0121] With reference to Fig. 17B, a Northern blot analysis of EST72223 and MIR-98 transfections were performed, subsequently marking RNA by the MIR-98 and GAM-4 probes . Left, Northern reacted with MIR-98, Right, Northern reacted with GAM-4. The molecular Sizes of EST72223, MIR-98 and GAM-4 are indicated by arrows. Hela are control cells that have not been introduced to exogenous RNA. EST and MIR-98 Transfections are RNA obtained from Hela transfected with EST72223 and MIR-98, respectively. MIR-98 and EST are the transcripts used for the transfection experiment. The results indicate that EST72223, when transfected into Hela cells, is cut yielding known miRNA gene MIR-98 and novel miRNA gene GAM-4.

[0122] Referring to Figs. 17A and 17B, the following technical methods used are specified as follows: Transcript preparations: Digoxigenin (DIG) labeled transcripts were prepared from EST72223 (TIGER), MIR98 and predicted precursor hairpins by using a DIG RNA labeling kit (Roche Molecular Biochemicals) according to the manufacture"s

protocol. Briefly, PCR products with T7 promoter at the 5" end or T3 promoter at the 3"end were prepared from each DNA in order to use it as a template to prepare sense and antisense transcripts, respectively.

[0123] MIR-98 was amplified using EST72223 as a templet with T7miR98 forward primer: 5-"TAATACGACTCACTATAGGGTGAGGTAGTAAGTTGTATTGTT-3"and T3miR98 revse primer: 5"-AATTAACCCTCACTAAAGGGAAAGTAGTAAGTTGTATAGTT-3"EST72223 was amplified with T7-EST 72223 forward primer:5"-TAATACGACTCACTATAGGCCCTTATTAGAGGATTCTGCT-3"and T3-EST72223 reverse primer:5"-AATTAACCCTCACTAAAGGTTTTTTTTTCCTGAGACAGAGT-3" Bet-4 was amplified using EST72223 as a templet with Bet-4 forward primer: 5"-GAGGCAGGAGAATTGCTTGA- 3" and T3-EST72223 reverse primer:5"-AATTAACCCTCACTAAAGGCCTGAGACAGAGTCTTGCTC-3"The PCR products were cleaned and used for DIG-labeled or unlabeled transcription reactions with the appropriate polymerase. For transfection experiments, CAP reaction was performed by using a mMassage mMachine kit (Ambion).

[0124] Transfection procedure: Transfection of Hela cells was performed by using TransMessenger reagent (Qiagen) according to the manufacture"s protocol. Briefly, Hela cells were seeded to 1-2x 10^6 cells per plate a day before transfection. Two µg RNA transcripts were mixed with 8µl Enhancer in a final volume of 100µl, mixed and incubated at room temperature for 5 min. 16µl TransMessenger reagent was added to the RNA-Enhancer, mixed and incubated for additional 10 min. Cell plates were washed with sterile PBS twice and then incubated with the transfection mix diluted with 2.5 ml DMEM medium without serum. Cells were incubated with transfection mix for three hours under their normal growth condition (370C and 5% CO2) before the transfection mix was removed and a fresh DMEM medium containing serum was added to the cells. Cells were left to grow 48 hours before harvesting.

[0125] *Northern analysis:*RNAs were extracted from cells by using Tri-reagent according to the manufacture"s protocol. The RNAs were dissolved in water and heated to 650C to disrupt any association of the 25nt RNA with larger RNA molecules. RNA were placed on ice and incubated for 30 min with PEG (MW=8000) in a final concentration of 5% and NaCl in a final concentration of 0.5M to precipitate

high molecular weight nucleic acid. The RNAs were centrifuged at 10,000xg for 10 min to pellet the high molecular weight nucleic acid. The supernatant containing the low molecular weight RNAs was collected and three volumes of ethanol was added. The RNAs were placed at -200C for at least two hours and then centrifuged at 10,000xg for 10 min. The pellets were dissolved in Urea-TBE buffer (1Xtbe, 7M urea) for further analysis by a Northern blot.

[0126] RNA samples were boiled for 5 min before loading on 15%-8% polyacrylamide (19:1) gels containing 7M urea and 1xTBE. Gels were run in 1xTBE at a constant voltage of 300V and then transferred into a nylon membrane. The membrane was exposed to 3min ultraviolet light to cross link the RNAs to the membrane. Hybridization was performed overnight with DIG-labeled probes at 420C. Membranes were washed twice with SSCx2 and 0.2% SDS for 10 min. at 420C and then washed twice with SSCx0.5 for 5 min at room temperature. The membrane was then developed by using a DIG luminescent detection kit (Roche) using anti DIG and CSPD reaction, according to the manufacture"s protocol.

[0127] Reference is now made to Fig. 8, which is a simplified dia-

gram describing each of a plurality of novel bioinformatically detected genes of the present invention, referred to here as Genomic Address Messenger (GAM) genes, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0128] GAM is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM was detected is described hereinabove with reference to Figs. 2-8.

[0129] GAM GENE and GAM TARGET GENE are human genes contained in the human genome.

[0130] GAM GENE encodes a GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM PRECURSOR RNA does not encode a protein.

[0131] GAM PRECURSOR RNA folds onto itself, forming GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof. By inversed-reversed

is meant a sequence which is reversed and wherein each nucleotide is replaced by a complementary nucleotide, as is well known in the art (e.g. ATGGC is the inversed-reversed sequence of GCCAT).

[0132] An enzyme complex designated DICER COMPLEX, dices the GAM FOLDED PRECURSOR RNA into GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins.

[0133] GAM TARGET GENE encodes a corresponding messenger RNA, GAM TARGET RNA. GAM TARGET RNA comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0134] GAM RNA binds complementarily to one or more target binding sites located in untranslated regions of GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM RNA is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illus-

tration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM RNA may have a different number of target binding sites in untranslated regions of a GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0135] The complementary binding of GAM RNA to target binding sites on GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM TARGET RNA into GAM TARGET PROTEIN. GAM TARGET PROTEIN is therefore outlined by a broken line.

[0136] It is appreciated that GAM TARGET GENE in fact represents a plurality of GAM target genes. The mRNA of each one of this plurality of GAM target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM RNA, and which when bound by GAM RNA causes inhibition of translation of respective one or more GAM target proteins.

[0137] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM GENE on one or more GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0138] It is yet further appreciated that specific functions, and accordingly utilities, of GAM correlate with, and may be deduced from, the identity of the target genes which GAM binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0139] Nucleotide sequences of the GAM PRECURSOR RNA, and of the diced GAM RNA, and a schematic representation of the secondary folding of GAM FOLDED PRECURSOR RNA of

each of the plurality of GAM GENEs described by Fig. 8 are further described hereinbelow with reference to Table.

[0140] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM RNA are described hereinbelow with reference to Table.

[0141]

[0142] Fig. 8 further provides a conceptual description of a novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 24 (GAM24) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0143] GAM24 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM24 was detected is described hereinabove with reference to Figs. 2-8.

[0144] GAM24 gene, herein designated GAM GENE, and GAM24 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0145] GAM24 gene, herein designated GAM GENE, encodes a

GAM24 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM24 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM24 precursor RNA is designated SEQ ID:1, and is provided hereinbelow with reference to the sequence listing part.

[0146] GAM24 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM24 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0147] An enzyme complex designated DICER COMPLEX, dices the GAM24 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM24 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured

RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM24 RNA is designated SEQ ID:2, and is provided hereinbelow with reference to the sequence listing part.

[0148] GAM24 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM24 target RNA, herein designated GAM TARGET RNA. GAM24 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0149] GAM24 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM24 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM24 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM24 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM24 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0150] The complementary binding of GAM24 RNA, herein designated GAM RNA, to target binding sites on GAM24 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM24 target RNA, herein designated GAM TARGET RNA, into GAM24 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0151] It is appreciated that GAM24 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM24 target genes. The mRNA of each one of this plurality of GAM24 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM24 RNA, herein designated GAM RNA, and which when bound by GAM24 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM24 target proteins.

[0152] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM24 gene, herein designated GAM GENE, on one or more GAM24 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0153] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM24 correlate with, and may be deduced from, the identity of the target genes which GAM24 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0154] Nucleotide sequences of the GAM24 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM24 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM24 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM24 are further described hereinbelow with reference to Table Table1.

[0155] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM24 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0156]

[0157] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 25 (GAM25) gene, which modulates expression of respective target genes thereof, the function and utility of which

target genes is known in the art.

[0158] GAM25 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM25 was detected is described hereinabove with reference to Figs. 2-8.

[0159] GAM25 gene, herein designated GAM GENE, and GAM25 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0160] GAM25 gene, herein designated GAM GENE, encodes a GAM25 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM25 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM25 precursor RNA is designated SEQ ID:11, and is provided hereinbelow with reference to the sequence listing part.

[0161] GAM25 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM25 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0162] An enzyme complex designated DICER COMPLEX, dices the GAM25 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM25 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM25 RNA is designated SEQ ID:12, and is provided hereinbelow with reference to the sequence listing part.

[0163] GAM25 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM25 target RNA, herein designated GAM TARGET RNA. GAM25 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0164] GAM25 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM25 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM25 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM25 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM25 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0165] The complementary binding of GAM25 RNA, herein designated GAM RNA, to target binding sites on GAM25 target RNA, herein designated GAM TARGET RNA, such as BIND-

ING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM25 target RNA, herein designated GAM TARGET RNA, into GAM25 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0166] It is appreciated that GAM25 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM25 target genes. The mRNA of each one of this plurality of GAM25 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM25 RNA, herein designated GAM RNA, and which when bound by GAM25 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM25 target proteins.

[0167] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM25 gene, herein designated GAM GENE, on one or more GAM25 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site

has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0168] It is yet further appreciated that specific functions, and accordingly utilities, of GAM25 correlate with, and may be deduced from, the identity of the target genes which GAM25 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0169] Nucleotide sequences of the GAM25 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM25 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM25 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM25 are further described hereinbelow with reference to Table Table1.

[0170] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM25 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0171]

[0172] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 26 (GAM26) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0173] GAM26 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM26 was detected is described hereinabove with reference to Figs. 2-8.

[0174] GAM26 gene, herein designated GAM GENE, and GAM26 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0175] GAM26 gene, herein designated GAM GENE, encodes a GAM26 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM26 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM26 precursor RNA is designated SEQ ID:36, and is provided hereinbelow with reference to the sequence listing part.

[0176] GAM26 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM26 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0177] An enzyme complex designated DICER COMPLEX, dices the GAM26 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM26 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM26 RNA is designated SEQ ID:37, and is provided hereinbelow with

reference to the sequence listing part.

[0178] GAM26 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM26 target RNA, herein designated GAM TARGET RNA. GAM26 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0179] GAM26 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM26 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM26 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM26 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM26 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0180] The complementary binding of GAM26 RNA, herein designated GAM RNA, to target binding sites on GAM26 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM26 target RNA, herein designated GAM TARGET RNA, into GAM26 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0181] It is appreciated that GAM26 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM26 target genes. The mRNA of each one of this plurality of GAM26 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM26 RNA, herein designated GAM RNA, and which when bound by GAM26 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM26 tar-

get proteins.

[0182] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM26 gene, herein designated GAM GENE, on one or more GAM26 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0183] It is yet further appreciated that specific functions, and accordingly utilities, of GAM26 correlate with, and may be deduced from, the identity of the target genes which GAM26 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0184] Nucleotide sequences of the GAM26 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM26 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM26 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM26 are further described hereinbelow with reference to Table Table1.

[0185] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM26 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0186]

[0187] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 27 (GAM27) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0188] GAM27 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM27 was detected is described hereinabove with reference to Figs. 2-8.

[0189] GAM27 gene, herein designated GAM GENE, and GAM27 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0190] GAM27 gene, herein designated GAM GENE, encodes a GAM27 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM27 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM27 precursor RNA is designated SEQ ID:46, and is provided hereinbelow with reference to the sequence listing part.

[0191] GAM27 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM27 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0192] An enzyme complex designated DICER COMPLEX, dices

the GAM27 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM27 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM27 RNA is designated SEQ ID:47, and is provided hereinbelow with reference to the sequence listing part.

[0193] GAM27 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM27 target RNA, herein designated GAM TARGET RNA. GAM27 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0194] GAM27 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM27 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM27

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM27 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM27 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0195] The complementary binding of GAM27 RNA, herein designated GAM RNA, to target binding sites on GAM27 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM27 target RNA, herein designated GAM TARGET RNA, into GAM27 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0196] It is appreciated that GAM27 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM27 target genes. The mRNA of each one of this plurality of GAM27 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM27 RNA, herein designated GAM RNA, and which when bound by GAM27 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM27 target proteins.

[0197] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM27 gene, herein designated GAM GENE, on one or more GAM27 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complemen-

tary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0198] It is yet further appreciated that specific functions, and accordingly utilities, of GAM27 correlate with, and may be deduced from, the identity of the target genes which GAM27 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0199] Nucleotide sequences of the GAM27 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM27 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM27 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM27 are further described hereinbelow with reference to Table Table1.

[0200] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM27 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0201]

[0202] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 28 (GAM28) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0203] GAM28 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM28 was detected is described hereinabove with reference to Figs. 2-8.

[0204] GAM28 gene, herein designated GAM GENE, and GAM28 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0205] GAM28 gene, herein designated GAM GENE, encodes a GAM28 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM28 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM28 precursor RNA is designated SEQ ID:54, and is provided hereinbelow with reference to the sequence listing part.

[0206] GAM28 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM28 folded precur-

sor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0207] An enzyme complex designated DICER COMPLEX, dices the GAM28 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM28 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 30%) nucleotide sequence of GAM28 RNA is designated SEQ ID:55, and is provided hereinbelow with reference to the sequence listing part.

[0208] GAM28 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM28 target RNA, herein designated GAM TARGET RNA. GAM28 target RNA, herein designated GAM TARGET RNA, com-

prises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0209] GAM28 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM28 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM28 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM28 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM28 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[0210] The complementary binding of GAM28 RNA, herein designated GAM RNA, to target binding sites on GAM28 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM28 target RNA, herein designated GAM TARGET RNA, into GAM28 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0211] It is appreciated that GAM28 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM28 target genes. The mRNA of each one of this plurality of GAM28 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM28 RNA, herein designated GAM RNA, and which when bound by GAM28 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM28 target proteins.

[0212] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM28 gene, herein designated GAM GENE, on one or

more GAM28 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0213] It is yet further appreciated that specific functions, and accordingly utilities, of GAM28 correlate with, and may be deduced from, the identity of the target genes which GAM28 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0214] Nucleotide sequences of the GAM28 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM28 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM28 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM28 are further described

hereinbelow with reference to Table Table1.

[0215] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM28 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0216]

[0217] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 29 (GAM29) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0218] GAM29 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM29 was detected is described hereinabove with reference to Figs. 2-8.

[0219] GAM29 gene, herein designated GAM GENE, and GAM29 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0220] GAM29 gene, herein designated GAM GENE, encodes a GAM29 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM29 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM29 precursor RNA is designated SEQ ID:67, and is provided hereinbelow with reference to the sequence listing part.

[0221] GAM29 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM29 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0222] An enzyme complex designated DICER COMPLEX, dices the GAM29 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM29 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is

catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 81%) nucleotide sequence of GAM29 RNA is designated SEQ ID:68, and is provided hereinbelow with reference to the sequence listing part.

[0223] GAM29 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM29 target RNA, herein designated GAM TARGET RNA. GAM29 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0224] GAM29 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM29 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM29 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM29 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM29 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0225] The complementary binding of GAM29 RNA, herein designated GAM RNA, to target binding sites on GAM29 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM29 target RNA, herein designated GAM TARGET RNA, into GAM29 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0226] It is appreciated that GAM29 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM29 target genes. The mRNA of each one of this plurality of GAM29 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM29 RNA, herein designated GAM RNA, and which when bound by GAM29 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM29 target proteins.

[0227] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM29 gene, herein designated GAM GENE, on one or more GAM29 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0228] It is yet further appreciated that specific functions, and accordingly utilities, of GAM29 correlate with, and may be

deduced from, the identity of the target genes which GAM29 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0229] Nucleotide sequences of the GAM29 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM29 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM29 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM29 are further described hereinbelow with reference to Table Table1.

[0230] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM29 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0231]

[0232] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 30 (GAM30) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0233] GAM30 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM30 was detected is described hereinabove with reference to Figs. 2-8.

[0234] GAM30 gene, herein designated GAM GENE, and GAM30 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0235] GAM30 gene, herein designated GAM GENE, encodes a GAM30 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM30 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM30 precursor RNA is designated SEQ ID:97, and is provided hereinbelow with reference to the sequence listing part.

[0236] GAM30 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM30 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0237] An enzyme complex designated DICER COMPLEX, dices the GAM30 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM30 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 29%) nucleotide sequence of GAM30 RNA is designated SEQ ID:98, and is provided hereinbelow with reference to the sequence listing part.

[0238] GAM30 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM30 target RNA, herein designated GAM TARGET RNA. GAM30 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0239] GAM30 RNA, herein designated GAM RNA, binds comple-

mentarily to one or more target binding sites located in untranslated regions of GAM30 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM30 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM30 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM30 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0240] The complementary binding of GAM30 RNA, herein designated GAM RNA, to target binding sites on GAM30 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits

translation of GAM30 target RNA, herein designated GAM TARGET RNA, into GAM30 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0241] It is appreciated that GAM30 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM30 target genes. The mRNA of each one of this plurality of GAM30 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM30 RNA, herein designated GAM RNA, and which when bound by GAM30 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM30 target proteins.

[0242] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM30 gene, herein designated GAM GENE, on one or more GAM30 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known

miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0243] It is yet further appreciated that specific functions, and accordingly utilities, of GAM30 correlate with, and may be deduced from, the identity of the target genes which GAM30 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0244] Nucleotide sequences of the GAM30 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM30 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM30 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM30 are further described hereinbelow with reference to Table Table1.

[0245] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM30 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0246]

[0247] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 31 (GAM31) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0248] GAM31 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM31 was detected is described hereinabove with reference to Figs. 2-8.

[0249] GAM31 gene, herein designated GAM GENE, and GAM31 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0250] GAM31 gene, herein designated GAM GENE, encodes a GAM31 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM31 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM31 precursor RNA is designated

SEQ ID:119, and is provided hereinbelow with reference to the sequence listing part.

[0251] GAM31 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM31 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0252] An enzyme complex designated DICER COMPLEX, dices the GAM31 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM31 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM31 RNA is designated SEQ ID:120, and is provided hereinbelow with reference to the sequence listing part.

[0253] GAM31 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM31 target RNA, herein designated GAM TARGET RNA. GAM31 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0254] GAM31 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM31 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM31 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM31 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM31 tar-

get RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0255] The complementary binding of GAM31 RNA, herein designated GAM RNA, to target binding sites on GAM31 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM31 target RNA, herein designated GAM TARGET RNA, into GAM31 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0256] It is appreciated that GAM31 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM31 target genes. The mRNA of each one of this plurality of GAM31 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM31 RNA, herein designated GAM RNA, and which when bound by GAM31 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM31 target proteins.

[0257] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM31 gene, herein designated GAM GENE, on one or more GAM31 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0258] It is yet further appreciated that specific functions, and accordingly utilities, of GAM31 correlate with, and may be deduced from, the identity of the target genes which GAM31 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0259] Nucleotide sequences of the GAM31 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM31 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM31 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM31 are further described hereinbelow with reference to Table Table1.

[0260] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM31 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0261]

[0262] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 32 (GAM32) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0263] GAM32 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM32 was detected is described hereinabove with reference to Figs. 2-8.

[0264] GAM32 gene, herein designated GAM GENE, and GAM32

target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0265] GAM32 gene, herein designated GAM GENE, encodes a GAM32 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM32 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM32 precursor RNA is designated SEQ ID:134, and is provided hereinbelow with reference to the sequence listing part.

[0266] GAM32 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM32 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0267] An enzyme complex designated DICER COMPLEX, dices the GAM32 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, into GAM32 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM32 RNA is designated SEQ ID:135, and is provided hereinbelow with reference to the sequence listing part.

[0268] GAM32 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM32 target RNA, herein designated GAM TARGET RNA. GAM32 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0269] GAM32 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM32 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM32 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM32 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM32 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0270] The complementary binding of GAM32 RNA, herein designated GAM RNA, to target binding sites on GAM32 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM32 target RNA, herein designated GAM TARGET RNA, into GAM32 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0271] It is appreciated that GAM32 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM32 target genes. The mRNA of each one of this plurality of GAM32 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM32 RNA, herein designated GAM RNA, and which when bound by GAM32 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM32 target proteins.

[0272] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM32 gene, herein designated GAM GENE, on one or more GAM32 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not

yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0273] It is yet further appreciated that specific functions, and accordingly utilities, of GAM32 correlate with, and may be deduced from, the identity of the target genes which GAM32 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0274] Nucleotide sequences of the GAM32 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM32 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM32 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM32 are further described hereinbelow with reference to Table Table1.

[0275] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM32 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0276]

[0277] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 33 (GAM33) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0278] GAM33 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM33 was detected is described hereinabove with reference to Figs. 2-8.

[0279] GAM33 gene, herein designated GAM GENE, and GAM33 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0280] GAM33 gene, herein designated GAM GENE, encodes a GAM33 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM33 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM33 precursor RNA is designated SEQ ID:160, and is provided hereinbelow with reference to the sequence listing part.

[0281] GAM33 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM33 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0282] An enzyme complex designated DICER COMPLEX, dices the GAM33 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM33 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM33 RNA is designated SEQ ID:161, and is provided hereinbelow with reference to the sequence listing part.

[0283] GAM33 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM33 target RNA, herein designated GAM TARGET RNA. GAM33 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein

coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0284] GAM33 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM33 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM33 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM33 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM33 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0285] The complementary binding of GAM33 RNA, herein designated GAM RNA, to target binding sites on GAM33 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM33 target RNA, herein designated GAM TARGET RNA, into GAM33 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0286] It is appreciated that GAM33 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM33 target genes. The mRNA of each one of this plurality of GAM33 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM33 RNA, herein designated GAM RNA, and which when bound by GAM33 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM33 target proteins.

[0287] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM33 gene, herein designated GAM GENE, on one or more GAM33 target gene, herein designated GAM TARGET

GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0288] It is yet further appreciated that specific functions, and accordingly utilities, of GAM33 correlate with, and may be deduced from, the identity of the target genes which GAM33 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0289] Nucleotide sequences of the GAM33 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM33 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM33 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM33 are further described hereinbelow with reference to Table Table1.

[0290] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM33 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0291]

[0292] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 34 (GAM34) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0293] GAM34 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM34 was detected is described hereinabove with reference to Figs. 2-8.

[0294] GAM34 gene, herein designated GAM GENE, and GAM34 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0295] GAM34 gene, herein designated GAM GENE, encodes a GAM34 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM34 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM34 precursor RNA is designated SEQ ID:177, and is provided hereinbelow with reference to the sequence listing part.

[0296] GAM34 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM34 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0297] An enzyme complex designated DICER COMPLEX, dices the GAM34 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM34 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme

called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM34 RNA is designated SEQ ID:178, and is provided hereinbelow with reference to the sequence listing part.

[0298] GAM34 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM34 target RNA, herein designated GAM TARGET RNA. GAM34 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0299] GAM34 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM34 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM34 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM34 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM34 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0300] The complementary binding of GAM34 RNA, herein designated GAM RNA, to target binding sites on GAM34 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM34 target RNA, herein designated GAM TARGET RNA, into GAM34 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0301] It is appreciated that GAM34 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM34 target genes. The mRNA of each one of this plurality of GAM34 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM34 RNA,

herein designated GAM RNA, and which when bound by GAM34 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM34 target proteins.

[0302] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM34 gene, herein designated GAM GENE, on one or more GAM34 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0303] It is yet further appreciated that specific functions, and accordingly utilities, of GAM34 correlate with, and may be deduced from, the identity of the target genes which

GAM34 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0304] Nucleotide sequences of the GAM34 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM34 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM34 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM34 are further described hereinbelow with reference to Table Table1.

[0305] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM34 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0306]

[0307] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 35 (GAM35) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0308] GAM35 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM35 was detected is described hereinabove with reference to Figs. 2-8.

[0309] GAM35 gene, herein designated GAM GENE, and GAM35 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0310] GAM35 gene, herein designated GAM GENE, encodes a GAM35 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM35 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM35 precursor RNA is designated SEQ ID:188, and is provided hereinbelow with reference to the sequence listing part.

[0311] GAM35 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM35 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[0312] An enzyme complex designated DICER COMPLEX, dices the GAM35 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM35 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 27%) nucleotide sequence of GAM35 RNA is designated SEQ ID:189, and is provided hereinbelow with reference to the sequence listing part.

[0313] GAM35 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM35 target RNA, herein designated GAM TARGET RNA. GAM35 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0314] GAM35 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM35 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM35 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM35 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM35 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0315] The complementary binding of GAM35 RNA, herein designated GAM RNA, to target binding sites on GAM35 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM35 target RNA, herein designated GAM

TARGET RNA, into GAM35 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0316] It is appreciated that GAM35 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM35 target genes. The mRNA of each one of this plurality of GAM35 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM35 RNA, herein designated GAM RNA, and which when bound by GAM35 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM35 target proteins.

[0317] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM35 gene, herein designated GAM GENE, on one or more GAM35 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other re-

cently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0318] It is yet further appreciated that specific functions, and accordingly utilities, of GAM35 correlate with, and may be deduced from, the identity of the target genes which GAM35 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0319] Nucleotide sequences of the GAM35 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM35 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM35 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM35 are further described hereinbelow with reference to Table Table1.

[0320] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM35 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[0321]

[0322] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 36 (GAM36) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0323] GAM36 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM36 was detected is described hereinabove with reference to Figs. 2-8.

[0324] GAM36 gene, herein designated GAM GENE, and GAM36 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0325] GAM36 gene, herein designated GAM GENE, encodes a GAM36 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM36 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM36 precursor RNA is designated SEQ ID:208, and is provided hereinbelow with reference to

the sequence listing part.

[0326] GAM36 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM36 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0327] An enzyme complex designated DICER COMPLEX, dices the GAM36 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM36 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 39%) nucleotide sequence of GAM36 RNA is designated SEQ ID:209, and is provided hereinbelow with reference to the sequence listing part.

[0328] GAM36 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM36 target RNA, herein designated GAM TARGET RNA. GAM36 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0329] GAM36 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM36 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM36 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM36 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM36 target RNA, herein designated GAM TARGET RNA. It is further

appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0330] The complementary binding of GAM36 RNA, herein designated GAM RNA, to target binding sites on GAM36 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM36 target RNA, herein designated GAM TARGET RNA, into GAM36 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0331] It is appreciated that GAM36 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM36 target genes. The mRNA of each one of this plurality of GAM36 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM36 RNA, herein designated GAM RNA, and which when bound by GAM36 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM36 target proteins.

[0332] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM36 gene, herein designated GAM GENE, on one or more GAM36 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0333] It is yet further appreciated that specific functions, and accordingly utilities, of GAM36 correlate with, and may be deduced from, the identity of the target genes which GAM36 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0334] Nucleotide sequences of the GAM36 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM36 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM36 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM36 are further described hereinbelow with reference to Table Table1.

[0335] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM36 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0336]

[0337] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 37 (GAM37) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0338] GAM37 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM37 was detected is described hereinabove with reference to Figs. 2-8.

[0339] GAM37 gene, herein designated GAM GENE, and GAM37 target gene, herein designated GAM TARGET GENE, are

human genes contained in the human genome.

[0340] GAM37 gene, herein designated GAM GENE, encodes a GAM37 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM37 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM37 precursor RNA is designated SEQ ID:214, and is provided hereinbelow with reference to the sequence listing part.

[0341] GAM37 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM37 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0342] An enzyme complex designated DICER COMPLEX, dices the GAM37 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM37 RNA, herein desig-

nated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM37 RNA is designated SEQ ID:215, and is provided hereinbelow with reference to the sequence listing part.

[0343] GAM37 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM37 target RNA, herein designated GAM TARGET RNA. GAM37 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0344] GAM37 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM37 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM37 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM37 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM37 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0345] The complementary binding of GAM37 RNA, herein designated GAM RNA, to target binding sites on GAM37 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM37 target RNA, herein designated GAM TARGET RNA, into GAM37 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0346] It is appreciated that GAM37 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM37 target genes. The mRNA of each one of this plurality of GAM37 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM37 RNA, herein designated GAM RNA, and which when bound by GAM37 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM37 target proteins.

[0347] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM37 gene, herein designated GAM GENE, on one or more GAM37 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny

RNA world, Science 294,779 (2001)).

[0348] It is yet further appreciated that specific functions, and accordingly utilities, of GAM37 correlate with, and may be deduced from, the identity of the target genes which GAM37 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0349] Nucleotide sequences of the GAM37 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM37 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM37 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM37 are further described hereinbelow with reference to Table Table1.

[0350] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM37 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0351]

[0352] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

38 (GAM38) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0353] GAM38 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM38 was detected is described hereinabove with reference to Figs. 2-8.

[0354] GAM38 gene, herein designated GAM GENE, and GAM38 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0355] GAM38 gene, herein designated GAM GENE, encodes a GAM38 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM38 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM38 precursor RNA is designated SEQ ID:235, and is provided hereinbelow with reference to the sequence listing part.

[0356] GAM38 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM38 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0357] An enzyme complex designated DICER COMPLEX, dices the GAM38 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM38 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM38 RNA is designated SEQ ID:236, and is provided hereinbelow with reference to the sequence listing part.

[0358] GAM38 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM38 target RNA, herein designated GAM TARGET RNA. GAM38 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding re-

gion and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0359] GAM38 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM38 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM38 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM38 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM38 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0360] The complementary binding of GAM38 RNA, herein desig-

nated GAM RNA, to target binding sites on GAM38 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM38 target RNA, herein designated GAM TARGET RNA, into GAM38 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0361] It is appreciated that GAM38 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM38 target genes. The mRNA of each one of this plurality of GAM38 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM38 RNA, herein designated GAM RNA, and which when bound by GAM38 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM38 target proteins.

[0362] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM38 gene, herein designated GAM GENE, on one or more GAM38 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As

mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0363] It is yet further appreciated that specific functions, and accordingly utilities, of GAM38 correlate with, and may be deduced from, the identity of the target genes which GAM38 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0364] Nucleotide sequences of the GAM38 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM38 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM38 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM38 are further described hereinbelow with reference to Table Table1.

[0365] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM38 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0366]

[0367] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 39 (GAM39) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0368] GAM39 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM39 was detected is described hereinabove with reference to Figs. 2-8.

[0369] GAM39 gene, herein designated GAM GENE, and GAM39 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0370] GAM39 gene, herein designated GAM GENE, encodes a GAM39 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM39 precursor RNA, herein designated

GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM39 precursor RNA is designated SEQ ID:245, and is provided hereinbelow with reference to the sequence listing part.

[0371] GAM39 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM39 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0372] An enzyme complex designated DICER COMPLEX, dices the GAM39 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM39 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A

probable (over 64%) nucleotide sequence of GAM39 RNA is designated SEQ ID:246, and is provided hereinbelow with reference to the sequence listing part.

[0373] GAM39 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM39 target RNA, herein designated GAM TARGET RNA. GAM39 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0374] GAM39 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM39 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM39 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM39 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM39 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0375] The complementary binding of GAM39 RNA, herein designated GAM RNA, to target binding sites on GAM39 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM39 target RNA, herein designated GAM TARGET RNA, into GAM39 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0376] It is appreciated that GAM39 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM39 target genes. The mRNA of each one of this plurality of GAM39 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM39 RNA, herein designated GAM RNA, and which when bound by

GAM39 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM39 target proteins.

[0377] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM39 gene, herein designated GAM GENE, on one or more GAM39 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0378] It is yet further appreciated that specific functions, and accordingly utilities, of GAM39 correlate with, and may be deduced from, the identity of the target genes which GAM39 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[0379] Nucleotide sequences of the GAM39 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM39 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM39 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM39 are further described hereinbelow with reference to Table Table1.

[0380] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM39 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0381]

[0382] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 40 (GAM40) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0383] GAM40 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM40 was detected is described hereinabove with reference to Figs. 2-8.

[0384] GAM40 gene, herein designated GAM GENE, and GAM40 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0385] GAM40 gene, herein designated GAM GENE, encodes a GAM40 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM40 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM40 precursor RNA is designated SEQ ID:259, and is provided hereinbelow with reference to the sequence listing part.

[0386] GAM40 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM40 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[0387] An enzyme complex designated DICER COMPLEX, dices the GAM40 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM40 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM40 RNA is designated SEQ ID:260, and is provided hereinbelow with reference to the sequence listing part.

[0388] GAM40 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM40 target RNA, herein designated GAM TARGET RNA. GAM40 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0389] GAM40 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM40 target RNA, herein desig-

nated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM40 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM40 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM40 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0390] The complementary binding of GAM40 RNA, herein designated GAM RNA, to target binding sites on GAM40 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM40 target RNA, herein designated GAM TARGET RNA, into GAM40 target protein, herein desig-

nated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0391] It is appreciated that GAM40 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM40 target genes. The mRNA of each one of this plurality of GAM40 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM40 RNA, herein designated GAM RNA, and which when bound by GAM40 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM40 target proteins.

[0392] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM40 gene, herein designated GAM GENE, on one or more GAM40 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those

skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0393] It is yet further appreciated that specific functions, and accordingly utilities, of GAM40 correlate with, and may be deduced from, the identity of the target genes which GAM40 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0394] Nucleotide sequences of the GAM40 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM40 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM40 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM40 are further described hereinbelow with reference to Table Table1.

[0395] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM40 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0396]

[0397] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 41 (GAM41) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0398] GAM41 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM41 was detected is described hereinabove with reference to Figs. 2-8.

[0399] GAM41 gene, herein designated GAM GENE, and GAM41 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0400] GAM41 gene, herein designated GAM GENE, encodes a GAM41 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM41 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM41 precursor RNA is designated SEQ ID:263, and is provided hereinbelow with reference to the sequence listing part.

[0401] GAM41 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM41 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0402] An enzyme complex designated DICER COMPLEX, dices the GAM41 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM41 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM41 RNA is designated SEQ ID:264, and is provided hereinbelow with reference to the sequence listing part.

[0403] GAM41 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM41

target RNA, herein designated GAM TARGET RNA. GAM41 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0404] GAM41 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM41 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM41 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM41 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM41 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites

in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0405] The complementary binding of GAM41 RNA, herein designated GAM RNA, to target binding sites on GAM41 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM41 target RNA, herein designated GAM TARGET RNA, into GAM41 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0406] It is appreciated that GAM41 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM41 target genes. The mRNA of each one of this plurality of GAM41 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM41 RNA, herein designated GAM RNA, and which when bound by GAM41 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM41 target proteins.

[0407] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM41 gene, herein designated GAM GENE, on one or more GAM41 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0408] It is yet further appreciated that specific functions, and accordingly utilities, of GAM41 correlate with, and may be deduced from, the identity of the target genes which GAM41 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0409] Nucleotide sequences of the GAM41 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM41 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM41 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM41 are further described hereinbelow with reference to Table Table1.

[0410] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM41 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0411]

[0412] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 42 (GAM42) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0413] GAM42 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM42 was detected is described hereinabove with reference to Figs. 2-8.

[0414] GAM42 gene, herein designated GAM GENE, and GAM42 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0415] GAM42 gene, herein designated GAM GENE, encodes a GAM42 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM42 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM42 precursor RNA is designated SEQ ID:283, and is provided hereinbelow with reference to the sequence listing part.

[0416] GAM42 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM42 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0417] An enzyme complex designated DICER COMPLEX, dices the GAM42 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM42 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA seg-

ment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM42 RNA is designated SEQ ID:284, and is provided hereinbelow with reference to the sequence listing part.

[0418] GAM42 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM42 target RNA, herein designated GAM TARGET RNA. GAM42 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0419] GAM42 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM42 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM42 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM42 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM42 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0420] The complementary binding of GAM42 RNA, herein designated GAM RNA, to target binding sites on GAM42 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM42 target RNA, herein designated GAM TARGET RNA, into GAM42 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0421] It is appreciated that GAM42 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM42 target genes. The mRNA of each one of this plu-

rality of GAM42 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM42 RNA, herein designated GAM RNA, and which when bound by GAM42 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM42 target proteins.

[0422] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM42 gene, herein designated GAM GENE, on one or more GAM42 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0423] It is yet further appreciated that specific functions, and accordingly utilities, of GAM42 correlate with, and may be deduced from, the identity of the target genes which GAM42 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0424] Nucleotide sequences of the GAM42 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM42 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM42 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM42 are further described hereinbelow with reference to Table Table1.

[0425] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM42 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0426]

[0427] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 43 (GAM43) gene, which modulates expression of respec-

tive target genes thereof, the function and utility of which target genes is known in the art.

[0428] GAM43 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM43 was detected is described hereinabove with reference to Figs. 2-8.

[0429] GAM43 gene, herein designated GAM GENE, and GAM43 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0430] GAM43 gene, herein designated GAM GENE, encodes a GAM43 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM43 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM43 precursor RNA is designated SEQ ID:300, and is provided hereinbelow with reference to the sequence listing part.

[0431] GAM43 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM43 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0432] An enzyme complex designated DICER COMPLEX, dices the GAM43 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM43 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM43 RNA is designated SEQ ID:301, and is provided hereinbelow with reference to the sequence listing part.

[0433] GAM43 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM43 target RNA, herein designated GAM TARGET RNA. GAM43 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PRO-

TEIN CODING and 3UTR respectively.

[0434] GAM43 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM43 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM43 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM43 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM43 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0435] The complementary binding of GAM43 RNA, herein designated GAM RNA, to target binding sites on GAM43 target

RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM43 target RNA, herein designated GAM TARGET RNA, into GAM43 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0436] It is appreciated that GAM43 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM43 target genes. The mRNA of each one of this plurality of GAM43 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM43 RNA, herein designated GAM RNA, and which when bound by GAM43 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM43 target proteins.

[0437] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM43 gene, herein designated GAM GENE, on one or more GAM43 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background

section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0438] It is yet further appreciated that specific functions, and accordingly utilities, of GAM43 correlate with, and may be deduced from, the identity of the target genes which GAM43 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0439] Nucleotide sequences of the GAM43 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM43 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM43 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM43 are further described hereinbelow with reference to Table Table1.

[0440] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM43 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0441]

[0442] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 44 (GAM44) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0443] GAM44 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM44 was detected is described hereinabove with reference to Figs. 2-8.

[0444] GAM44 gene, herein designated GAM GENE, and GAM44 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0445] GAM44 gene, herein designated GAM GENE, encodes a GAM44 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM44 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nu-

cleotide sequence identical or highly similar to the nucleotide sequence of GAM44 precursor RNA is designated SEQ ID:309, and is provided hereinbelow with reference to the sequence listing part.

[0446] GAM44 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM44 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0447] An enzyme complex designated DICER COMPLEX, dices the GAM44 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM44 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM44 RNA is

designated SEQ ID:310, and is provided hereinbelow with reference to the sequence listing part.

[0448] GAM44 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM44 target RNA, herein designated GAM TARGET RNA. GAM44 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0449] GAM44 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM44 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM44 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM44 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM44 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0450] The complementary binding of GAM44 RNA, herein designated GAM RNA, to target binding sites on GAM44 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM44 target RNA, herein designated GAM TARGET RNA, into GAM44 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0451] It is appreciated that GAM44 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM44 target genes. The mRNA of each one of this plurality of GAM44 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM44 RNA, herein designated GAM RNA, and which when bound by GAM44 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM44 target proteins.

[0452] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM44 gene, herein designated GAM GENE, on one or more GAM44 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0453] It is yet further appreciated that specific functions, and accordingly utilities, of GAM44 correlate with, and may be deduced from, the identity of the target genes which GAM44 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0454] Nucleotide sequences of the GAM44 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM44 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM44 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM44 are further described hereinbelow with reference to Table Table1.

[0455] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM44 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0456]

[0457] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 45 (GAM45) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0458] GAM45 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM45 was detected is described hereinabove

with reference to Figs. 2-8.

[0459] GAM45 gene, herein designated GAM GENE, and GAM45 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0460] GAM45 gene, herein designated GAM GENE, encodes a GAM45 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM45 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM45 precursor RNA is designated SEQ ID:337, and is provided hereinbelow with reference to the sequence listing part.

[0461] GAM45 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM45 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0462] An enzyme complex designated DICER COMPLEX, dices the GAM45 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM45 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 17%) nucleotide sequence of GAM45 RNA is designated SEQ ID:338, and is provided hereinbelow with reference to the sequence listing part.

[0463] GAM45 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM45 target RNA, herein designated GAM TARGET RNA. GAM45 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0464] GAM45 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM45 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM45 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM45 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM45 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0465] The complementary binding of GAM45 RNA, herein designated GAM RNA, to target binding sites on GAM45 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM45 target RNA, herein designated GAM TARGET RNA, into GAM45 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is there-

fore outlined by a broken line.

[0466] It is appreciated that GAM45 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM45 target genes. The mRNA of each one of this plurality of GAM45 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM45 RNA, herein designated GAM RNA, and which when bound by GAM45 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM45 target proteins.

[0467] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM45 gene, herein designated GAM GENE, on one or more GAM45 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes

by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0468] It is yet further appreciated that specific functions, and accordingly utilities, of GAM45 correlate with, and may be deduced from, the identity of the target genes which GAM45 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0469] Nucleotide sequences of the GAM45 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM45 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM45 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM45 are further described hereinbelow with reference to Table Table1.

[0470] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM45 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0471]

[0472] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 46 (GAM46) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0473] GAM46 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM46 was detected is described hereinabove with reference to Figs. 2-8.

[0474] GAM46 gene, herein designated GAM GENE, and GAM46 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0475] GAM46 gene, herein designated GAM GENE, encodes a GAM46 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM46 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM46 precursor RNA is designated SEQ ID:365, and is provided hereinbelow with reference to the sequence listing part.

[0476] GAM46 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM46 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0477] An enzyme complex designated DICER COMPLEX, dices the GAM46 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM46 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 80%) nucleotide sequence of GAM46 RNA is designated SEQ ID:366, and is provided hereinbelow with reference to the sequence listing part.

[0478] GAM46 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM46 target RNA, herein designated GAM TARGET RNA. GAM46

target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0479] GAM46 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM46 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM46 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM46 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM46 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0480] The complementary binding of GAM46 RNA, herein designated GAM RNA, to target binding sites on GAM46 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM46 target RNA, herein designated GAM TARGET RNA, into GAM46 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0481] It is appreciated that GAM46 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM46 target genes. The mRNA of each one of this plurality of GAM46 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM46 RNA, herein designated GAM RNA, and which when bound by GAM46 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM46 target proteins.

[0482] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM46 gene, herein designated GAM GENE, on one or more GAM46 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0483] It is yet further appreciated that specific functions, and accordingly utilities, of GAM46 correlate with, and may be deduced from, the identity of the target genes which GAM46 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0484] Nucleotide sequences of the GAM46 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM46 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM46 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM46 are further described hereinbelow with reference to Table Table1.

[0485] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM46 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0486]

[0487] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 47 (GAM47) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0488] GAM47 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM47 was detected is described hereinabove with reference to Figs. 2-8.

[0489] GAM47 gene, herein designated GAM GENE, and GAM47 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0490] GAM47 gene, herein designated GAM GENE, encodes a

GAM47 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM47 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM47 precursor RNA is designated SEQ ID:387, and is provided hereinbelow with reference to the sequence listing part.

[0491] GAM47 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM47 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0492] An enzyme complex designated DICER COMPLEX, dices the GAM47 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM47 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured

RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 42%) nucleotide sequence of GAM47 RNA is designated SEQ ID:388, and is provided hereinbelow with reference to the sequence listing part.

[0493] GAM47 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM47 target RNA, herein designated GAM TARGET RNA. GAM47 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0494] GAM47 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM47 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM47 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM47 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM47 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0495] The complementary binding of GAM47 RNA, herein designated GAM RNA, to target binding sites on GAM47 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM47 target RNA, herein designated GAM TARGET RNA, into GAM47 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0496] It is appreciated that GAM47 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM47 target genes. The mRNA of each one of this plurality of GAM47 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM47 RNA, herein designated GAM RNA, and which when bound by GAM47 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM47 target proteins.

[0497] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM47 gene, herein designated GAM GENE, on one or more GAM47 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0498] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM47 correlate with, and may be deduced from, the identity of the target genes which GAM47 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0499] Nucleotide sequences of the GAM47 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM47 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM47 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM47 are further described hereinbelow with reference to Table Table1.

[0500] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM47 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0501]

[0502] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 48 (GAM48) gene, which modulates expression of respective target genes thereof, the function and utility of which

target genes is known in the art.

[0503] GAM48 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM48 was detected is described hereinabove with reference to Figs. 2-8.

[0504] GAM48 gene, herein designated GAM GENE, and GAM48 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0505] GAM48 gene, herein designated GAM GENE, encodes a GAM48 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM48 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM48 precursor RNA is designated SEQ ID:422, and is provided hereinbelow with reference to the sequence listing part.

[0506] GAM48 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM48 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0507] An enzyme complex designated DICER COMPLEX, dices the GAM48 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM48 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM48 RNA is designated SEQ ID:423, and is provided hereinbelow with reference to the sequence listing part.

[0508] GAM48 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM48 target RNA, herein designated GAM TARGET RNA. GAM48 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0509] GAM48 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM48 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM48 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM48 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM48 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0510] The complementary binding of GAM48 RNA, herein designated GAM RNA, to target binding sites on GAM48 target RNA, herein designated GAM TARGET RNA, such as BIND-

ING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM48 target RNA, herein designated GAM TARGET RNA, into GAM48 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0511] It is appreciated that GAM48 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM48 target genes. The mRNA of each one of this plurality of GAM48 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM48 RNA, herein designated GAM RNA, and which when bound by GAM48 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM48 target proteins.

[0512] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM48 gene, herein designated GAM GENE, on one or more GAM48 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site

has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0513] It is yet further appreciated that specific functions, and accordingly utilities, of GAM48 correlate with, and may be deduced from, the identity of the target genes which GAM48 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0514] Nucleotide sequences of the GAM48 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM48 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM48 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM48 are further described hereinbelow with reference to Table Table1.

[0515] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM48 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0516]

[0517] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 49 (GAM49) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0518] GAM49 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM49 was detected is described hereinabove with reference to Figs. 2-8.

[0519] GAM49 gene, herein designated GAM GENE, and GAM49 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0520] GAM49 gene, herein designated GAM GENE, encodes a GAM49 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM49 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM49 precursor RNA is designated SEQ ID:429, and is provided hereinbelow with reference to the sequence listing part.

[0521] GAM49 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM49 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0522] An enzyme complex designated DICER COMPLEX, dices the GAM49 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM49 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM49 RNA is designated SEQ ID:430, and is provided hereinbelow with

reference to the sequence listing part.

[0523] GAM49 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM49 target RNA, herein designated GAM TARGET RNA. GAM49 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0524] GAM49 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM49 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM49 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM49 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM49 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0525] The complementary binding of GAM49 RNA, herein designated GAM RNA, to target binding sites on GAM49 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM49 target RNA, herein designated GAM TARGET RNA, into GAM49 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0526] It is appreciated that GAM49 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM49 target genes. The mRNA of each one of this plurality of GAM49 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM49 RNA, herein designated GAM RNA, and which when bound by GAM49 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM49 tar-

get proteins.

[0527] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM49 gene, herein designated GAM GENE, on one or more GAM49 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0528] It is yet further appreciated that specific functions, and accordingly utilities, of GAM49 correlate with, and may be deduced from, the identity of the target genes which GAM49 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0529] Nucleotide sequences of the GAM49 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM49 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM49 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM49 are further described hereinbelow with reference to Table Table1.

[0530] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM49 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0531]

[0532] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 50 (GAM50) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0533] GAM50 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM50 was detected is described hereinabove with reference to Figs. 2-8.

[0534] GAM50 gene, herein designated GAM GENE, and GAM50 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0535] GAM50 gene, herein designated GAM GENE, encodes a GAM50 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM50 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM50 precursor RNA is designated SEQ ID:453, and is provided hereinbelow with reference to the sequence listing part.

[0536] GAM50 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM50 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0537] An enzyme complex designated DICER COMPLEX, dices

the GAM50 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM50 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM50 RNA is designated SEQ ID:454, and is provided hereinbelow with reference to the sequence listing part.

[0538] GAM50 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM50 target RNA, herein designated GAM TARGET RNA. GAM50 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0539] GAM50 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM50 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM50

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM50 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM50 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0540] The complementary binding of GAM50 RNA, herein designated GAM RNA, to target binding sites on GAM50 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM50 target RNA, herein designated GAM TARGET RNA, into GAM50 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0541] It is appreciated that GAM50 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM50 target genes. The mRNA of each one of this plurality of GAM50 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM50 RNA, herein designated GAM RNA, and which when bound by GAM50 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM50 target proteins.

[0542] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM50 gene, herein designated GAM GENE, on one or more GAM50 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complemen-

tary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0543] It is yet further appreciated that specific functions, and accordingly utilities, of GAM50 correlate with, and may be deduced from, the identity of the target genes which GAM50 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0544] Nucleotide sequences of the GAM50 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM50 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM50 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM50 are further described hereinbelow with reference to Table Table1.

[0545] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM50 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0546]

[0547] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 51 (GAM51) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0548] GAM51 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM51 was detected is described hereinabove with reference to Figs. 2-8.

[0549] GAM51 gene, herein designated GAM GENE, and GAM51 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0550] GAM51 gene, herein designated GAM GENE, encodes a GAM51 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM51 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM51 precursor RNA is designated SEQ ID:459, and is provided hereinbelow with reference to the sequence listing part.

[0551] GAM51 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM51 folded precur-

sor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0552] An enzyme complex designated DICER COMPLEX, dices the GAM51 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM51 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 26%) nucleotide sequence of GAM51 RNA is designated SEQ ID:460, and is provided hereinbelow with reference to the sequence listing part.

[0553] GAM51 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM51 target RNA, herein designated GAM TARGET RNA. GAM51 target RNA, herein designated GAM TARGET RNA, com-

prises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0554] GAM51 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM51 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM51 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM51 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM51 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[0555] The complementary binding of GAM51 RNA, herein designated GAM RNA, to target binding sites on GAM51 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM51 target RNA, herein designated GAM TARGET RNA, into GAM51 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0556] It is appreciated that GAM51 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM51 target genes. The mRNA of each one of this plurality of GAM51 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM51 RNA, herein designated GAM RNA, and which when bound by GAM51 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM51 target proteins.

[0557] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM51 gene, herein designated GAM GENE, on one or

more GAM51 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0558] It is yet further appreciated that specific functions, and accordingly utilities, of GAM51 correlate with, and may be deduced from, the identity of the target genes which GAM51 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0559] Nucleotide sequences of the GAM51 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM51 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM51 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM51 are further described

hereinbelow with reference to Table Table1.

[0560] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM51 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0561]

[0562] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 52 (GAM52) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0563] GAM52 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM52 was detected is described hereinabove with reference to Figs. 2-8.

[0564] GAM52 gene, herein designated GAM GENE, and GAM52 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0565] GAM52 gene, herein designated GAM GENE, encodes a GAM52 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM52 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM52 precursor RNA is designated SEQ ID:480, and is provided hereinbelow with reference to the sequence listing part.

[0566] GAM52 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM52 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0567] An enzyme complex designated DICER COMPLEX, dices the GAM52 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM52 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is

catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 41%) nucleotide sequence of GAM52 RNA is designated SEQ ID:481, and is provided hereinbelow with reference to the sequence listing part.

[0568] GAM52 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM52 target RNA, herein designated GAM TARGET RNA. GAM52 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0569] GAM52 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM52 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM52 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM52 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM52 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0570] The complementary binding of GAM52 RNA, herein designated GAM RNA, to target binding sites on GAM52 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM52 target RNA, herein designated GAM TARGET RNA, into GAM52 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0571] It is appreciated that GAM52 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM52 target genes. The mRNA of each one of this plurality of GAM52 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM52 RNA, herein designated GAM RNA, and which when bound by GAM52 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM52 target proteins.

[0572] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM52 gene, herein designated GAM GENE, on one or more GAM52 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0573] It is yet further appreciated that specific functions, and accordingly utilities, of GAM52 correlate with, and may be

deduced from, the identity of the target genes which GAM52 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0574] Nucleotide sequences of the GAM52 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM52 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM52 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM52 are further described hereinbelow with reference to Table Table1.

[0575] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM52 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0576]

[0577] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 53 (GAM53) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0578] GAM53 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM53 was detected is described hereinabove with reference to Figs. 2-8.

[0579] GAM53 gene, herein designated GAM GENE, and GAM53 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0580] GAM53 gene, herein designated GAM GENE, encodes a GAM53 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM53 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM53 precursor RNA is designated SEQ ID:522, and is provided hereinbelow with reference to the sequence listing part.

[0581] GAM53 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM53 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0582] An enzyme complex designated DICER COMPLEX, dices the GAM53 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM53 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM53 RNA is designated SEQ ID:523, and is provided hereinbelow with reference to the sequence listing part.

[0583] GAM53 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM53 target RNA, herein designated GAM TARGET RNA. GAM53 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0584] GAM53 RNA, herein designated GAM RNA, binds comple-

mentarily to one or more target binding sites located in untranslated regions of GAM53 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM53 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM53 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM53 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0585] The complementary binding of GAM53 RNA, herein designated GAM RNA, to target binding sites on GAM53 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits

translation of GAM53 target RNA, herein designated GAM TARGET RNA, into GAM53 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0586] It is appreciated that GAM53 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM53 target genes. The mRNA of each one of this plurality of GAM53 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM53 RNA, herein designated GAM RNA, and which when bound by GAM53 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM53 target proteins.

[0587] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM53 gene, herein designated GAM GENE, on one or more GAM53 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known

miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0588] It is yet further appreciated that specific functions, and accordingly utilities, of GAM53 correlate with, and may be deduced from, the identity of the target genes which GAM53 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0589] Nucleotide sequences of the GAM53 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM53 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM53 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM53 are further described hereinbelow with reference to Table Table1.

[0590] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM53 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0591]

[0592] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 54 (GAM54) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0593] GAM54 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM54 was detected is described hereinabove with reference to Figs. 2-8.

[0594] GAM54 gene, herein designated GAM GENE, and GAM54 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0595] GAM54 gene, herein designated GAM GENE, encodes a GAM54 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM54 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM54 precursor RNA is designated

SEQ ID:531, and is provided hereinbelow with reference to the sequence listing part.

[0596] GAM54 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM54 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0597] An enzyme complex designated DICER COMPLEX, dices the GAM54 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM54 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM54 RNA is designated SEQ ID:532, and is provided hereinbelow with reference to the sequence listing part.

[0598] GAM54 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM54 target RNA, herein designated GAM TARGET RNA. GAM54 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0599] GAM54 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM54 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM54 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM54 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM54 tar-

get RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0600] The complementary binding of GAM54 RNA, herein designated GAM RNA, to target binding sites on GAM54 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM54 target RNA, herein designated GAM TARGET RNA, into GAM54 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0601] It is appreciated that GAM54 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM54 target genes. The mRNA of each one of this plurality of GAM54 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM54 RNA, herein designated GAM RNA, and which when bound by GAM54 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM54 target proteins.

[0602] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM54 gene, herein designated GAM GENE, on one or more GAM54 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0603] It is yet further appreciated that specific functions, and accordingly utilities, of GAM54 correlate with, and may be deduced from, the identity of the target genes which GAM54 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0604] Nucleotide sequences of the GAM54 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM54 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM54 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM54 are further described hereinbelow with reference to Table Table1.

[0605] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM54 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0606]

[0607] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 55 (GAM55) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0608] GAM55 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM55 was detected is described hereinabove with reference to Figs. 2-8.

[0609] GAM55 gene, herein designated GAM GENE, and GAM55

target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0610] GAM55 gene, herein designated GAM GENE, encodes a GAM55 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM55 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM55 precursor RNA is designated SEQ ID:545, and is provided hereinbelow with reference to the sequence listing part.

[0611] GAM55 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM55 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0612] An enzyme complex designated DICER COMPLEX, dices the GAM55 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, into GAM55 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM55 RNA is designated SEQ ID:546, and is provided hereinbelow with reference to the sequence listing part.

[0613] GAM55 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM55 target RNA, herein designated GAM TARGET RNA. GAM55 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0614] GAM55 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM55 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM55 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM55 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM55 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0615] The complementary binding of GAM55 RNA, herein designated GAM RNA, to target binding sites on GAM55 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM55 target RNA, herein designated GAM TARGET RNA, into GAM55 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0616] It is appreciated that GAM55 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM55 target genes. The mRNA of each one of this plurality of GAM55 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM55 RNA, herein designated GAM RNA, and which when bound by GAM55 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM55 target proteins.

[0617] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM55 gene, herein designated GAM GENE, on one or more GAM55 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not

yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0618] It is yet further appreciated that specific functions, and accordingly utilities, of GAM55 correlate with, and may be deduced from, the identity of the target genes which GAM55 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0619] Nucleotide sequences of the GAM55 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM55 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM55 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM55 are further described hereinbelow with reference to Table Table1.

[0620] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM55 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0621]

[0622] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 56 (GAM56) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0623] GAM56 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM56 was detected is described hereinabove with reference to Figs. 2-8.

[0624] GAM56 gene, herein designated GAM GENE, and GAM56 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0625] GAM56 gene, herein designated GAM GENE, encodes a GAM56 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM56 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM56 precursor RNA is designated SEQ ID:556, and is provided hereinbelow with reference to the sequence listing part.

[0626] GAM56 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM56 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0627] An enzyme complex designated DICER COMPLEX, dices the GAM56 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM56 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM56 RNA is designated SEQ ID:557, and is provided hereinbelow with reference to the sequence listing part.

[0628] GAM56 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM56 target RNA, herein designated GAM TARGET RNA. GAM56 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein

coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0629] GAM56 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM56 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM56 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM56 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM56 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0630] The complementary binding of GAM56 RNA, herein designated GAM RNA, to target binding sites on GAM56 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM56 target RNA, herein designated GAM TARGET RNA, into GAM56 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0631] It is appreciated that GAM56 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM56 target genes. The mRNA of each one of this plurality of GAM56 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM56 RNA, herein designated GAM RNA, and which when bound by GAM56 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM56 target proteins.

[0632] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM56 gene, herein designated GAM GENE, on one or more GAM56 target gene, herein designated GAM TARGET

GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0633] It is yet further appreciated that specific functions, and accordingly utilities, of GAM56 correlate with, and may be deduced from, the identity of the target genes which GAM56 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0634] Nucleotide sequences of the GAM56 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM56 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM56 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM56 are further described hereinbelow with reference to Table Table1.

[0635] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM56 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0636]

[0637] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 57 (GAM57) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0638] GAM57 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM57 was detected is described hereinabove with reference to Figs. 2-8.

[0639] GAM57 gene, herein designated GAM GENE, and GAM57 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0640] GAM57 gene, herein designated GAM GENE, encodes a GAM57 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM57 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM57 precursor RNA is designated SEQ ID:561, and is provided hereinbelow with reference to the sequence listing part.

[0641] GAM57 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM57 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0642] An enzyme complex designated DICER COMPLEX, dices the GAM57 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM57 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme

called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM57 RNA is designated SEQ ID:562, and is provided hereinbelow with reference to the sequence listing part.

[0643] GAM57 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM57 target RNA, herein designated GAM TARGET RNA. GAM57 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0644] GAM57 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM57 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM57 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM57 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM57 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0645] The complementary binding of GAM57 RNA, herein designated GAM RNA, to target binding sites on GAM57 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM57 target RNA, herein designated GAM TARGET RNA, into GAM57 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0646] It is appreciated that GAM57 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM57 target genes. The mRNA of each one of this plurality of GAM57 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM57 RNA,

herein designated GAM RNA, and which when bound by GAM57 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM57 target proteins.

[0647] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM57 gene, herein designated GAM GENE, on one or more GAM57 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0648] It is yet further appreciated that specific functions, and accordingly utilities, of GAM57 correlate with, and may be deduced from, the identity of the target genes which

GAM57 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0649] Nucleotide sequences of the GAM57 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM57 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM57 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM57 are further described hereinbelow with reference to Table Table1.

[0650] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM57 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0651]

[0652] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 58 (GAM58) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0653] GAM58 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM58 was detected is described hereinabove with reference to Figs. 2-8.

[0654] GAM58 gene, herein designated GAM GENE, and GAM58 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0655] GAM58 gene, herein designated GAM GENE, encodes a GAM58 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM58 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM58 precursor RNA is designated SEQ ID:573, and is provided hereinbelow with reference to the sequence listing part.

[0656] GAM58 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM58 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[0657] An enzyme complex designated DICER COMPLEX, dices the GAM58 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM58 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM58 RNA is designated SEQ ID:574, and is provided hereinbelow with reference to the sequence listing part.

[0658] GAM58 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM58 target RNA, herein designated GAM TARGET RNA. GAM58 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0659] GAM58 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM58 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM58 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM58 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM58 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0660] The complementary binding of GAM58 RNA, herein designated GAM RNA, to target binding sites on GAM58 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM58 target RNA, herein designated GAM

TARGET RNA, into GAM58 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0661] It is appreciated that GAM58 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM58 target genes. The mRNA of each one of this plurality of GAM58 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM58 RNA, herein designated GAM RNA, and which when bound by GAM58 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM58 target proteins.

[0662] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM58 gene, herein designated GAM GENE, on one or more GAM58 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other re-

cently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0663] It is yet further appreciated that specific functions, and accordingly utilities, of GAM58 correlate with, and may be deduced from, the identity of the target genes which GAM58 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0664] Nucleotide sequences of the GAM58 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM58 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM58 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM58 are further described hereinbelow with reference to Table Table1.

[0665] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM58 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[0666]

[0667] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 59 (GAM59) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0668] GAM59 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM59 was detected is described hereinabove with reference to Figs. 2-8.

[0669] GAM59 gene, herein designated GAM GENE, and GAM59 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0670] GAM59 gene, herein designated GAM GENE, encodes a GAM59 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM59 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM59 precursor RNA is designated SEQ ID:588, and is provided hereinbelow with reference to

the sequence listing part.

[0671] GAM59 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM59 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0672] An enzyme complex designated DICER COMPLEX, dices the GAM59 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM59 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM59 RNA is designated SEQ ID:589, and is provided hereinbelow with reference to the sequence listing part.

[0673] GAM59 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM59 target RNA, herein designated GAM TARGET RNA. GAM59 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0674] GAM59 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM59 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM59 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM59 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM59 target RNA, herein designated GAM TARGET RNA. It is further

appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0675] The complementary binding of GAM59 RNA, herein designated GAM RNA, to target binding sites on GAM59 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM59 target RNA, herein designated GAM TARGET RNA, into GAM59 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0676] It is appreciated that GAM59 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM59 target genes. The mRNA of each one of this plurality of GAM59 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM59 RNA, herein designated GAM RNA, and which when bound by GAM59 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM59 target proteins.

[0677] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM59 gene, herein designated GAM GENE, on one or more GAM59 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0678] It is yet further appreciated that specific functions, and accordingly utilities, of GAM59 correlate with, and may be deduced from, the identity of the target genes which GAM59 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0679] Nucleotide sequences of the GAM59 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM59 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM59 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM59 are further described hereinbelow with reference to Table Table1.

[0680] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM59 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0681]

[0682] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 60 (GAM60) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0683] GAM60 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM60 was detected is described hereinabove with reference to Figs. 2-8.

[0684] GAM60 gene, herein designated GAM GENE, and GAM60 target gene, herein designated GAM TARGET GENE, are

human genes contained in the human genome.

[0685] GAM60 gene, herein designated GAM GENE, encodes a GAM60 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM60 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM60 precursor RNA is designated SEQ ID:604, and is provided hereinbelow with reference to the sequence listing part.

[0686] GAM60 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM60 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0687] An enzyme complex designated DICER COMPLEX, dices the GAM60 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM60 RNA, herein desig-

nated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 40%) nucleotide sequence of GAM60 RNA is designated SEQ ID:605, and is provided hereinbelow with reference to the sequence listing part.

[0688] GAM60 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM60 target RNA, herein designated GAM TARGET RNA. GAM60 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0689] GAM60 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM60 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM60 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM60 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM60 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0690] The complementary binding of GAM60 RNA, herein designated GAM RNA, to target binding sites on GAM60 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM60 target RNA, herein designated GAM TARGET RNA, into GAM60 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0691] It is appreciated that GAM60 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM60 target genes. The mRNA of each one of this plurality of GAM60 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM60 RNA, herein designated GAM RNA, and which when bound by GAM60 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM60 target proteins.

[0692] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM60 gene, herein designated GAM GENE, on one or more GAM60 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny

RNA world, Science 294,779 (2001)).

[0693] It is yet further appreciated that specific functions, and accordingly utilities, of GAM60 correlate with, and may be deduced from, the identity of the target genes which GAM60 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0694] Nucleotide sequences of the GAM60 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM60 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM60 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM60 are further described hereinbelow with reference to Table Table1.

[0695] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM60 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0696]

[0697] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

61 (GAM61) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0698] GAM61 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM61 was detected is described hereinabove with reference to Figs. 2-8.

[0699] GAM61 gene, herein designated GAM GENE, and GAM61 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0700] GAM61 gene, herein designated GAM GENE, encodes a GAM61 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM61 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM61 precursor RNA is designated SEQ ID:617, and is provided hereinbelow with reference to the sequence listing part.

[0701] GAM61 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM61 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0702] An enzyme complex designated DICER COMPLEX, dices the GAM61 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM61 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM61 RNA is designated SEQ ID:618, and is provided hereinbelow with reference to the sequence listing part.

[0703] GAM61 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM61 target RNA, herein designated GAM TARGET RNA. GAM61 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding re-

gion and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0704] GAM61 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM61 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM61 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM61 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM61 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0705] The complementary binding of GAM61 RNA, herein desig-

nated GAM RNA, to target binding sites on GAM61 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM61 target RNA, herein designated GAM TARGET RNA, into GAM61 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0706] It is appreciated that GAM61 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM61 target genes. The mRNA of each one of this plurality of GAM61 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM61 RNA, herein designated GAM RNA, and which when bound by GAM61 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM61 target proteins.

[0707] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM61 gene, herein designated GAM GENE, on one or more GAM61 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As

mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0708] It is yet further appreciated that specific functions, and accordingly utilities, of GAM61 correlate with, and may be deduced from, the identity of the target genes which GAM61 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0709] Nucleotide sequences of the GAM61 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM61 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM61 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM61 are further described hereinbelow with reference to Table Table1.

[0710] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM61 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0711]

[0712] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 62 (GAM62) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0713] GAM62 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM62 was detected is described hereinabove with reference to Figs. 2-8.

[0714] GAM62 gene, herein designated GAM GENE, and GAM62 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0715] GAM62 gene, herein designated GAM GENE, encodes a GAM62 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM62 precursor RNA, herein designated

GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM62 precursor RNA is designated SEQ ID:630, and is provided hereinbelow with reference to the sequence listing part.

[0716] GAM62 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM62 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0717] An enzyme complex designated DICER COMPLEX, dices the GAM62 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM62 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A

probable (over 53%) nucleotide sequence of GAM62 RNA is designated SEQ ID:631, and is provided hereinbelow with reference to the sequence listing part.

[0718] GAM62 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM62 target RNA, herein designated GAM TARGET RNA. GAM62 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0719] GAM62 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM62 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM62 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM62 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM62 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0720] The complementary binding of GAM62 RNA, herein designated GAM RNA, to target binding sites on GAM62 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM62 target RNA, herein designated GAM TARGET RNA, into GAM62 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0721] It is appreciated that GAM62 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM62 target genes. The mRNA of each one of this plurality of GAM62 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM62 RNA, herein designated GAM RNA, and which when bound by

GAM62 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM62 target proteins.

[0722] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM62 gene, herein designated GAM GENE, on one or more GAM62 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0723] It is yet further appreciated that specific functions, and accordingly utilities, of GAM62 correlate with, and may be deduced from, the identity of the target genes which GAM62 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[0724] Nucleotide sequences of the GAM62 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM62 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM62 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM62 are further described hereinbelow with reference to Table Table1.

[0725] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM62 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0726]

[0727] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 63 (GAM63) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0728] GAM63 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM63 was detected is described hereinabove with reference to Figs. 2-8.

[0729] GAM63 gene, herein designated GAM GENE, and GAM63 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0730] GAM63 gene, herein designated GAM GENE, encodes a GAM63 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM63 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM63 precursor RNA is designated SEQ ID:652, and is provided hereinbelow with reference to the sequence listing part.

[0731] GAM63 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM63 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[0732] An enzyme complex designated DICER COMPLEX, dices the GAM63 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM63 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM63 RNA is designated SEQ ID:653, and is provided hereinbelow with reference to the sequence listing part.

[0733] GAM63 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM63 target RNA, herein designated GAM TARGET RNA. GAM63 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0734] GAM63 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM63 target RNA, herein desig-

nated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM63 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM63 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM63 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0735] The complementary binding of GAM63 RNA, herein designated GAM RNA, to target binding sites on GAM63 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM63 target RNA, herein designated GAM TARGET RNA, into GAM63 target protein, herein desig-

nated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0736] It is appreciated that GAM63 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM63 target genes. The mRNA of each one of this plurality of GAM63 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM63 RNA, herein designated GAM RNA, and which when bound by GAM63 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM63 target proteins.

[0737] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM63 gene, herein designated GAM GENE, on one or more GAM63 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those

skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0738] It is yet further appreciated that specific functions, and accordingly utilities, of GAM63 correlate with, and may be deduced from, the identity of the target genes which GAM63 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0739] Nucleotide sequences of the GAM63 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM63 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM63 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM63 are further described hereinbelow with reference to Table Table1.

[0740] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM63 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0741]

[0742] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 64 (GAM64) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0743] GAM64 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM64 was detected is described hereinabove with reference to Figs. 2-8.

[0744] GAM64 gene, herein designated GAM GENE, and GAM64 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0745] GAM64 gene, herein designated GAM GENE, encodes a GAM64 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM64 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM64 precursor RNA is designated SEQ ID:673, and is provided hereinbelow with reference to the sequence listing part.

[0746] GAM64 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM64 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0747] An enzyme complex designated DICER COMPLEX, dices the GAM64 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM64 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 38%) nucleotide sequence of GAM64 RNA is designated SEQ ID:674, and is provided hereinbelow with reference to the sequence listing part.

[0748] GAM64 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM64

target RNA, herein designated GAM TARGET RNA. GAM64 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0749] GAM64 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM64 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM64 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM64 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM64 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites

in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0750] The complementary binding of GAM64 RNA, herein designated GAM RNA, to target binding sites on GAM64 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM64 target RNA, herein designated GAM TARGET RNA, into GAM64 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0751] It is appreciated that GAM64 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM64 target genes. The mRNA of each one of this plurality of GAM64 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM64 RNA, herein designated GAM RNA, and which when bound by GAM64 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM64 target proteins.

[0752] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM64 gene, herein designated GAM GENE, on one or more GAM64 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0753] It is yet further appreciated that specific functions, and accordingly utilities, of GAM64 correlate with, and may be deduced from, the identity of the target genes which GAM64 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0754] Nucleotide sequences of the GAM64 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM64 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM64 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM64 are further described hereinbelow with reference to Table Table1.

[0755] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM64 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0756]

[0757] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 65 (GAM65) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0758] GAM65 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM65 was detected is described hereinabove with reference to Figs. 2-8.

[0759] GAM65 gene, herein designated GAM GENE, and GAM65 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0760] GAM65 gene, herein designated GAM GENE, encodes a GAM65 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM65 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM65 precursor RNA is designated SEQ ID:697, and is provided hereinbelow with reference to the sequence listing part.

[0761] GAM65 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM65 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0762] An enzyme complex designated DICER COMPLEX, dices the GAM65 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM65 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA seg-

ment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM65 RNA is designated SEQ ID:698, and is provided hereinbelow with reference to the sequence listing part.

[0763] GAM65 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM65 target RNA, herein designated GAM TARGET RNA. GAM65 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0764] GAM65 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM65 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM65 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM65 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM65 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0765] The complementary binding of GAM65 RNA, herein designated GAM RNA, to target binding sites on GAM65 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM65 target RNA, herein designated GAM TARGET RNA, into GAM65 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0766] It is appreciated that GAM65 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM65 target genes. The mRNA of each one of this plu-

rality of GAM65 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM65 RNA, herein designated GAM RNA, and which when bound by GAM65 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM65 target proteins.

[0767] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM65 gene, herein designated GAM GENE, on one or more GAM65 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0768] It is yet further appreciated that specific functions, and accordingly utilities, of GAM65 correlate with, and may be deduced from, the identity of the target genes which GAM65 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0769] Nucleotide sequences of the GAM65 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM65 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM65 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM65 are further described hereinbelow with reference to Table Table1.

[0770] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM65 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0771]

[0772] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 66 (GAM66) gene, which modulates expression of respec-

tive target genes thereof, the function and utility of which target genes is known in the art.

[0773] GAM66 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM66 was detected is described hereinabove with reference to Figs. 2-8.

[0774] GAM66 gene, herein designated GAM GENE, and GAM66 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0775] GAM66 gene, herein designated GAM GENE, encodes a GAM66 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM66 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM66 precursor RNA is designated SEQ ID:721, and is provided hereinbelow with reference to the sequence listing part.

[0776] GAM66 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM66 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0777] An enzyme complex designated DICER COMPLEX, dices the GAM66 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM66 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM66 RNA is designated SEQ ID:722, and is provided hereinbelow with reference to the sequence listing part.

[0778] GAM66 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM66 target RNA, herein designated GAM TARGET RNA. GAM66 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PRO-

TEIN CODING and 3UTR respectively.

[0779] GAM66 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM66 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM66 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM66 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM66 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0780] The complementary binding of GAM66 RNA, herein designated GAM RNA, to target binding sites on GAM66 target

RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM66 target RNA, herein designated GAM TARGET RNA, into GAM66 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0781] It is appreciated that GAM66 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM66 target genes. The mRNA of each one of this plurality of GAM66 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM66 RNA, herein designated GAM RNA, and which when bound by GAM66 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM66 target proteins.

[0782] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM66 gene, herein designated GAM GENE, on one or more GAM66 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background

section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0783] It is yet further appreciated that specific functions, and accordingly utilities, of GAM66 correlate with, and may be deduced from, the identity of the target genes which GAM66 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0784] Nucleotide sequences of the GAM66 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM66 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM66 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM66 are further described hereinbelow with reference to Table Table1.

[0785] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM66 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0786]

[0787] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 67 (GAM67) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0788] GAM67 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM67 was detected is described hereinabove with reference to Figs. 2-8.

[0789] GAM67 gene, herein designated GAM GENE, and GAM67 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0790] GAM67 gene, herein designated GAM GENE, encodes a GAM67 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM67 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nu-

cleotide sequence identical or highly similar to the nucleotide sequence of GAM67 precursor RNA is designated SEQ ID:737, and is provided hereinbelow with reference to the sequence listing part.

[0791] GAM67 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM67 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0792] An enzyme complex designated DICER COMPLEX, dices the GAM67 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM67 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 37%) nucleotide sequence of GAM67 RNA is

designated SEQ ID:738, and is provided hereinbelow with reference to the sequence listing part.

[0793] GAM67 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM67 target RNA, herein designated GAM TARGET RNA. GAM67 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0794] GAM67 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM67 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM67 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM67 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM67 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0795] The complementary binding of GAM67 RNA, herein designated GAM RNA, to target binding sites on GAM67 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM67 target RNA, herein designated GAM TARGET RNA, into GAM67 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0796] It is appreciated that GAM67 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM67 target genes. The mRNA of each one of this plurality of GAM67 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM67 RNA, herein designated GAM RNA, and which when bound by GAM67 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM67 target proteins.

[0797] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM67 gene, herein designated GAM GENE, on one or more GAM67 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0798] It is yet further appreciated that specific functions, and accordingly utilities, of GAM67 correlate with, and may be deduced from, the identity of the target genes which GAM67 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0799] Nucleotide sequences of the GAM67 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM67 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM67 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM67 are further described hereinbelow with reference to Table Table1.

[0800] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM67 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0801]

[0802] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 68 (GAM68) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0803] GAM68 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM68 was detected is described hereinabove

with reference to Figs. 2-8.

[0804] GAM68 gene, herein designated GAM GENE, and GAM68 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0805] GAM68 gene, herein designated GAM GENE, encodes a GAM68 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM68 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM68 precursor RNA is designated SEQ ID:748, and is provided hereinbelow with reference to the sequence listing part.

[0806] GAM68 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM68 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0807] An enzyme complex designated DICER COMPLEX, dices the GAM68 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM68 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 48%) nucleotide sequence of GAM68 RNA is designated SEQ ID:749, and is provided hereinbelow with reference to the sequence listing part.

[0808] GAM68 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM68 target RNA, herein designated GAM TARGET RNA. GAM68 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0809] GAM68 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM68 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM68 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM68 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM68 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0810] The complementary binding of GAM68 RNA, herein designated GAM RNA, to target binding sites on GAM68 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM68 target RNA, herein designated GAM TARGET RNA, into GAM68 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is there-

fore outlined by a broken line.

[0811] It is appreciated that GAM68 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM68 target genes. The mRNA of each one of this plurality of GAM68 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM68 RNA, herein designated GAM RNA, and which when bound by GAM68 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM68 target proteins.

[0812] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM68 gene, herein designated GAM GENE, on one or more GAM68 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes

by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0813] It is yet further appreciated that specific functions, and accordingly utilities, of GAM68 correlate with, and may be deduced from, the identity of the target genes which GAM68 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0814] Nucleotide sequences of the GAM68 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM68 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM68 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM68 are further described hereinbelow with reference to Table Table1.

[0815] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM68 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0816]

[0817] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 69 (GAM69) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0818] GAM69 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM69 was detected is described hereinabove with reference to Figs. 2-8.

[0819] GAM69 gene, herein designated GAM GENE, and GAM69 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0820] GAM69 gene, herein designated GAM GENE, encodes a GAM69 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM69 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM69 precursor RNA is designated SEQ ID:782, and is provided hereinbelow with reference to the sequence listing part.

[0821] GAM69 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM69 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0822] An enzyme complex designated DICER COMPLEX, dices the GAM69 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM69 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM69 RNA is designated SEQ ID:783, and is provided hereinbelow with reference to the sequence listing part.

[0823] GAM69 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM69 target RNA, herein designated GAM TARGET RNA. GAM69

target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0824] GAM69 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM69 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM69 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM69 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM69 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0825] The complementary binding of GAM69 RNA, herein designated GAM RNA, to target binding sites on GAM69 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM69 target RNA, herein designated GAM TARGET RNA, into GAM69 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0826] It is appreciated that GAM69 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM69 target genes. The mRNA of each one of this plurality of GAM69 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM69 RNA, herein designated GAM RNA, and which when bound by GAM69 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM69 target proteins.

[0827] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM69 gene, herein designated GAM GENE, on one or more GAM69 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0828] It is yet further appreciated that specific functions, and accordingly utilities, of GAM69 correlate with, and may be deduced from, the identity of the target genes which GAM69 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0829] Nucleotide sequences of the GAM69 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM69 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM69 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM69 are further described hereinbelow with reference to Table Table1.

[0830] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM69 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0831]

[0832] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 70 (GAM70) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0833] GAM70 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM70 was detected is described hereinabove with reference to Figs. 2-8.

[0834] GAM70 gene, herein designated GAM GENE, and GAM70 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0835] GAM70 gene, herein designated GAM GENE, encodes a

GAM70 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM70 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM70 precursor RNA is designated SEQ ID:792, and is provided hereinbelow with reference to the sequence listing part.

[0836] GAM70 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM70 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0837] An enzyme complex designated DICER COMPLEX, dices the GAM70 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM70 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured

RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM70 RNA is designated SEQ ID:793, and is provided hereinbelow with reference to the sequence listing part.

[0838] GAM70 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM70 target RNA, herein designated GAM TARGET RNA. GAM70 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0839] GAM70 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM70 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM70 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM70 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM70 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0840] The complementary binding of GAM70 RNA, herein designated GAM RNA, to target binding sites on GAM70 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM70 target RNA, herein designated GAM TARGET RNA, into GAM70 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0841] It is appreciated that GAM70 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM70 target genes. The mRNA of each one of this plurality of GAM70 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM70 RNA, herein designated GAM RNA, and which when bound by GAM70 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM70 target proteins.

[0842] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM70 gene, herein designated GAM GENE, on one or more GAM70 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0843] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM70 correlate with, and may be deduced from, the identity of the target genes which GAM70 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0844] Nucleotide sequences of the GAM70 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM70 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM70 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM70 are further described hereinbelow with reference to Table Table1.

[0845] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM70 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0846]

[0847] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 71 (GAM71) gene, which modulates expression of respective target genes thereof, the function and utility of which

target genes is known in the art.

[0848] GAM71 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM71 was detected is described hereinabove with reference to Figs. 2-8.

[0849] GAM71 gene, herein designated GAM GENE, and GAM71 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0850] GAM71 gene, herein designated GAM GENE, encodes a GAM71 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM71 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM71 precursor RNA is designated SEQ ID:818, and is provided hereinbelow with reference to the sequence listing part.

[0851] GAM71 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM71 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0852] An enzyme complex designated DICER COMPLEX, dices the GAM71 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM71 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM71 RNA is designated SEQ ID:819, and is provided hereinbelow with reference to the sequence listing part.

[0853] GAM71 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM71 target RNA, herein designated GAM TARGET RNA. GAM71 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0854] GAM71 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM71 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM71 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM71 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM71 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0855] The complementary binding of GAM71 RNA, herein designated GAM RNA, to target binding sites on GAM71 target RNA, herein designated GAM TARGET RNA, such as BIND-

ING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM71 target RNA, herein designated GAM TARGET RNA, into GAM71 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0856] It is appreciated that GAM71 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM71 target genes. The mRNA of each one of this plurality of GAM71 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM71 RNA, herein designated GAM RNA, and which when bound by GAM71 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM71 target proteins.

[0857] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM71 gene, herein designated GAM GENE, on one or more GAM71 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site

has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0858] It is yet further appreciated that specific functions, and accordingly utilities, of GAM71 correlate with, and may be deduced from, the identity of the target genes which GAM71 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0859] Nucleotide sequences of the GAM71 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM71 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM71 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM71 are further described hereinbelow with reference to Table Table1.

[0860] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM71 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0861]

[0862] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 72 (GAM72) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0863] GAM72 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM72 was detected is described hereinabove with reference to Figs. 2-8.

[0864] GAM72 gene, herein designated GAM GENE, and GAM72 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0865] GAM72 gene, herein designated GAM GENE, encodes a GAM72 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM72 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM72 precursor RNA is designated SEQ ID:835, and is provided hereinbelow with reference to the sequence listing part.

[0866] GAM72 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM72 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0867] An enzyme complex designated DICER COMPLEX, dices the GAM72 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM72 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM72 RNA is designated SEQ ID:836, and is provided hereinbelow with

reference to the sequence listing part.

[0868] GAM72 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM72 target RNA, herein designated GAM TARGET RNA. GAM72 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0869] GAM72 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM72 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM72 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM72 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM72 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0870] The complementary binding of GAM72 RNA, herein designated GAM RNA, to target binding sites on GAM72 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM72 target RNA, herein designated GAM TARGET RNA, into GAM72 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0871] It is appreciated that GAM72 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM72 target genes. The mRNA of each one of this plurality of GAM72 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM72 RNA, herein designated GAM RNA, and which when bound by GAM72 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM72 tar-

get proteins.

[0872] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM72 gene, herein designated GAM GENE, on one or more GAM72 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0873] It is yet further appreciated that specific functions, and accordingly utilities, of GAM72 correlate with, and may be deduced from, the identity of the target genes which GAM72 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0874] Nucleotide sequences of the GAM72 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM72 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM72 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM72 are further described hereinbelow with reference to Table Table1.

[0875] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM72 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0876]

[0877] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 73 (GAM73) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0878] GAM73 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM73 was detected is described hereinabove with reference to Figs. 2-8.

[0879] GAM73 gene, herein designated GAM GENE, and GAM73 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0880] GAM73 gene, herein designated GAM GENE, encodes a GAM73 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM73 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM73 precursor RNA is designated SEQ ID:845, and is provided hereinbelow with reference to the sequence listing part.

[0881] GAM73 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM73 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0882] An enzyme complex designated DICER COMPLEX, dices

the GAM73 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM73 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM73 RNA is designated SEQ ID:846, and is provided hereinbelow with reference to the sequence listing part.

[0883] GAM73 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM73 target RNA, herein designated GAM TARGET RNA. GAM73 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0884] GAM73 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM73 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM73

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM73 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM73 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0885] The complementary binding of GAM73 RNA, herein designated GAM RNA, to target binding sites on GAM73 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM73 target RNA, herein designated GAM TARGET RNA, into GAM73 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0886] It is appreciated that GAM73 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM73 target genes. The mRNA of each one of this plurality of GAM73 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM73 RNA, herein designated GAM RNA, and which when bound by GAM73 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM73 target proteins.

[0887] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM73 gene, herein designated GAM GENE, on one or more GAM73 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complemen-

tary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0888] It is yet further appreciated that specific functions, and accordingly utilities, of GAM73 correlate with, and may be deduced from, the identity of the target genes which GAM73 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0889] Nucleotide sequences of the GAM73 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM73 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM73 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM73 are further described hereinbelow with reference to Table Table1.

[0890] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM73 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0891]

[0892] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 74 (GAM74) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0893] GAM74 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM74 was detected is described hereinabove with reference to Figs. 2-8.

[0894] GAM74 gene, herein designated GAM GENE, and GAM74 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0895] GAM74 gene, herein designated GAM GENE, encodes a GAM74 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM74 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM74 precursor RNA is designated SEQ ID:862, and is provided hereinbelow with reference to the sequence listing part.

[0896] GAM74 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM74 folded precur-

sor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0897] An enzyme complex designated DICER COMPLEX, dices the GAM74 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM74 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 78%) nucleotide sequence of GAM74 RNA is designated SEQ ID:863, and is provided hereinbelow with reference to the sequence listing part.

[0898] GAM74 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM74 target RNA, herein designated GAM TARGET RNA. GAM74 target RNA, herein designated GAM TARGET RNA, com-

prises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0899] GAM74 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM74 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM74 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM74 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM74 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[0900] The complementary binding of GAM74 RNA, herein designated GAM RNA, to target binding sites on GAM74 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM74 target RNA, herein designated GAM TARGET RNA, into GAM74 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0901] It is appreciated that GAM74 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM74 target genes. The mRNA of each one of this plurality of GAM74 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM74 RNA, herein designated GAM RNA, and which when bound by GAM74 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM74 target proteins.

[0902] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM74 gene, herein designated GAM GENE, on one or

more GAM74 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0903] It is yet further appreciated that specific functions, and accordingly utilities, of GAM74 correlate with, and may be deduced from, the identity of the target genes which GAM74 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0904] Nucleotide sequences of the GAM74 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM74 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM74 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM74 are further described

hereinbelow with reference to Table Table1.

[0905] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM74 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0906]

[0907] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 75 (GAM75) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0908] GAM75 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM75 was detected is described hereinabove with reference to Figs. 2-8.

[0909] GAM75 gene, herein designated GAM GENE, and GAM75 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0910] GAM75 gene, herein designated GAM GENE, encodes a GAM75 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM75 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM75 precursor RNA is designated SEQ ID:876, and is provided hereinbelow with reference to the sequence listing part.

[0911] GAM75 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM75 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0912] An enzyme complex designated DICER COMPLEX, dices the GAM75 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM75 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is

catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM75 RNA is designated SEQ ID:877, and is provided hereinbelow with reference to the sequence listing part.

[0913] GAM75 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM75 target RNA, herein designated GAM TARGET RNA. GAM75 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0914] GAM75 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM75 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM75 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM75 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM75 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0915] The complementary binding of GAM75 RNA, herein designated GAM RNA, to target binding sites on GAM75 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM75 target RNA, herein designated GAM TARGET RNA, into GAM75 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0916] It is appreciated that GAM75 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM75 target genes. The mRNA of each one of this plurality of GAM75 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM75 RNA, herein designated GAM RNA, and which when bound by GAM75 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM75 target proteins.

[0917] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM75 gene, herein designated GAM GENE, on one or more GAM75 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0918] It is yet further appreciated that specific functions, and accordingly utilities, of GAM75 correlate with, and may be

deduced from, the identity of the target genes which GAM75 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0919] Nucleotide sequences of the GAM75 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM75 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM75 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM75 are further described hereinbelow with reference to Table Table1.

[0920] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM75 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0921]

[0922] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 76 (GAM76) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0923] GAM76 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM76 was detected is described hereinabove with reference to Figs. 2-8.

[0924] GAM76 gene, herein designated GAM GENE, and GAM76 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0925] GAM76 gene, herein designated GAM GENE, encodes a GAM76 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM76 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM76 precursor RNA is designated SEQ ID:905, and is provided hereinbelow with reference to the sequence listing part.

[0926] GAM76 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM76 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0927] An enzyme complex designated DICER COMPLEX, dices the GAM76 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM76 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM76 RNA is designated SEQ ID:906, and is provided hereinbelow with reference to the sequence listing part.

[0928] GAM76 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM76 target RNA, herein designated GAM TARGET RNA. GAM76 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0929] GAM76 RNA, herein designated GAM RNA, binds comple-

mentarily to one or more target binding sites located in untranslated regions of GAM76 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM76 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM76 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM76 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0930] The complementary binding of GAM76 RNA, herein designated GAM RNA, to target binding sites on GAM76 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits

translation of GAM76 target RNA, herein designated GAM TARGET RNA, into GAM76 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0931] It is appreciated that GAM76 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM76 target genes. The mRNA of each one of this plurality of GAM76 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM76 RNA, herein designated GAM RNA, and which when bound by GAM76 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM76 target proteins.

[0932] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM76 gene, herein designated GAM GENE, on one or more GAM76 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known

miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0933] It is yet further appreciated that specific functions, and accordingly utilities, of GAM76 correlate with, and may be deduced from, the identity of the target genes which GAM76 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0934] Nucleotide sequences of the GAM76 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM76 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM76 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM76 are further described hereinbelow with reference to Table Table1.

[0935] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM76 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0936]

[0937] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 77 (GAM77) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0938] GAM77 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM77 was detected is described hereinabove with reference to Figs. 2-8.

[0939] GAM77 gene, herein designated GAM GENE, and GAM77 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0940] GAM77 gene, herein designated GAM GENE, encodes a GAM77 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM77 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM77 precursor RNA is designated

SEQ ID:919, and is provided hereinbelow with reference to the sequence listing part.

[0941] GAM77 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM77 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0942] An enzyme complex designated DICER COMPLEX, dices the GAM77 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM77 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 91%) nucleotide sequence of GAM77 RNA is designated SEQ ID:920, and is provided hereinbelow with reference to the sequence listing part.

[0943] GAM77 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM77 target RNA, herein designated GAM TARGET RNA. GAM77 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0944] GAM77 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM77 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM77 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM77 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM77 tar-

get RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0945] The complementary binding of GAM77 RNA, herein designated GAM RNA, to target binding sites on GAM77 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM77 target RNA, herein designated GAM TARGET RNA, into GAM77 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0946] It is appreciated that GAM77 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM77 target genes. The mRNA of each one of this plurality of GAM77 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM77 RNA, herein designated GAM RNA, and which when bound by GAM77 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM77 target proteins.

[0947] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM77 gene, herein designated GAM GENE, on one or more GAM77 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0948] It is yet further appreciated that specific functions, and accordingly utilities, of GAM77 correlate with, and may be deduced from, the identity of the target genes which GAM77 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0949] Nucleotide sequences of the GAM77 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM77 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM77 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM77 are further described hereinbelow with reference to Table Table1.

[0950] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM77 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0951]

[0952] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 78 (GAM78) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0953] GAM78 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM78 was detected is described hereinabove with reference to Figs. 2-8.

[0954] GAM78 gene, herein designated GAM GENE, and GAM78

target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0955] GAM78 gene, herein designated GAM GENE, encodes a GAM78 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM78 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM78 precursor RNA is designated SEQ ID:938, and is provided hereinbelow with reference to the sequence listing part.

[0956] GAM78 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM78 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0957] An enzyme complex designated DICER COMPLEX, dices the GAM78 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, into GAM78 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 37%) nucleotide sequence of GAM78 RNA is designated SEQ ID:939, and is provided hereinbelow with reference to the sequence listing part.

[0958] GAM78 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM78 target RNA, herein designated GAM TARGET RNA. GAM78 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0959] GAM78 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM78 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM78 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM78 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM78 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0960] The complementary binding of GAM78 RNA, herein designated GAM RNA, to target binding sites on GAM78 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM78 target RNA, herein designated GAM TARGET RNA, into GAM78 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0961] It is appreciated that GAM78 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM78 target genes. The mRNA of each one of this plurality of GAM78 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM78 RNA, herein designated GAM RNA, and which when bound by GAM78 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM78 target proteins.

[0962] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM78 gene, herein designated GAM GENE, on one or more GAM78 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not

yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0963] It is yet further appreciated that specific functions, and accordingly utilities, of GAM78 correlate with, and may be deduced from, the identity of the target genes which GAM78 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0964] Nucleotide sequences of the GAM78 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM78 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM78 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM78 are further described hereinbelow with reference to Table Table1.

[0965] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM78 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0966]

[0967] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 79 (GAM79) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0968] GAM79 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM79 was detected is described hereinabove with reference to Figs. 2-8.

[0969] GAM79 gene, herein designated GAM GENE, and GAM79 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0970] GAM79 gene, herein designated GAM GENE, encodes a GAM79 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM79 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM79 precursor RNA is designated SEQ ID:952, and is provided hereinbelow with reference to the sequence listing part.

[0971] GAM79 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM79 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0972] An enzyme complex designated DICER COMPLEX, dices the GAM79 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM79 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM79 RNA is designated SEQ ID:953, and is provided hereinbelow with reference to the sequence listing part.

[0973] GAM79 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM79 target RNA, herein designated GAM TARGET RNA. GAM79 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein

coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0974] GAM79 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM79 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM79 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM79 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM79 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0975] The complementary binding of GAM79 RNA, herein designated GAM RNA, to target binding sites on GAM79 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM79 target RNA, herein designated GAM TARGET RNA, into GAM79 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0976] It is appreciated that GAM79 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM79 target genes. The mRNA of each one of this plurality of GAM79 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM79 RNA, herein designated GAM RNA, and which when bound by GAM79 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM79 target proteins.

[0977] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM79 gene, herein designated GAM GENE, on one or more GAM79 target gene, herein designated GAM TARGET

GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0978] It is yet further appreciated that specific functions, and accordingly utilities, of GAM79 correlate with, and may be deduced from, the identity of the target genes which GAM79 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0979] Nucleotide sequences of the GAM79 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM79 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM79 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM79 are further described hereinbelow with reference to Table Table1.

[0980] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM79 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0981]

[0982] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 80 (GAM80) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0983] GAM80 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM80 was detected is described hereinabove with reference to Figs. 2-8.

[0984] GAM80 gene, herein designated GAM GENE, and GAM80 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[0985] GAM80 gene, herein designated GAM GENE, encodes a GAM80 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM80 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM80 precursor RNA is designated SEQ ID:971, and is provided hereinbelow with reference to the sequence listing part.

[0986] GAM80 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM80 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[0987] An enzyme complex designated DICER COMPLEX, dices the GAM80 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM80 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme

called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM80 RNA is designated SEQ ID:972, and is provided hereinbelow with reference to the sequence listing part.

[0988] GAM80 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM80 target RNA, herein designated GAM TARGET RNA. GAM80 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[0989] GAM80 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM80 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM80 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM80 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM80 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[0990] The complementary binding of GAM80 RNA, herein designated GAM RNA, to target binding sites on GAM80 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM80 target RNA, herein designated GAM TARGET RNA, into GAM80 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[0991] It is appreciated that GAM80 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM80 target genes. The mRNA of each one of this plurality of GAM80 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM80 RNA,

herein designated GAM RNA, and which when bound by GAM80 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM80 target proteins.

[0992] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM80 gene, herein designated GAM GENE, on one or more GAM80 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[0993] It is yet further appreciated that specific functions, and accordingly utilities, of GAM80 correlate with, and may be deduced from, the identity of the target genes which

GAM80 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[0994] Nucleotide sequences of the GAM80 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM80 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM80 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM80 are further described hereinbelow with reference to Table Table1.

[0995] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM80 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[0996]

[0997] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 81 (GAM81) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[0998] GAM81 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM81 was detected is described hereinabove with reference to Figs. 2-8.

[0999] GAM81 gene, herein designated GAM GENE, and GAM81 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1000] GAM81 gene, herein designated GAM GENE, encodes a GAM81 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM81 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM81 precursor RNA is designated SEQ ID:997, and is provided hereinbelow with reference to the sequence listing part.

[1001] GAM81 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM81 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[1002] An enzyme complex designated DICER COMPLEX, dices the GAM81 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM81 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 35%) nucleotide sequence of GAM81 RNA is designated SEQ ID:998, and is provided hereinbelow with reference to the sequence listing part.

[1003] GAM81 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM81 target RNA, herein designated GAM TARGET RNA. GAM81 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1004] GAM81 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM81 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM81 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM81 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM81 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1005] The complementary binding of GAM81 RNA, herein designated GAM RNA, to target binding sites on GAM81 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM81 target RNA, herein designated GAM

TARGET RNA, into GAM81 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1006] It is appreciated that GAM81 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM81 target genes. The mRNA of each one of this plurality of GAM81 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM81 RNA, herein designated GAM RNA, and which when bound by GAM81 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM81 target proteins.

[1007] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM81 gene, herein designated GAM GENE, on one or more GAM81 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other re-

cently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1008] It is yet further appreciated that specific functions, and accordingly utilities, of GAM81 correlate with, and may be deduced from, the identity of the target genes which GAM81 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1009] Nucleotide sequences of the GAM81 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM81 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM81 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM81 are further described hereinbelow with reference to Table Table1.

[1010] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM81 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[1011]

[1012] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 82 (GAM82) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1013] GAM82 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM82 was detected is described hereinabove with reference to Figs. 2-8.

[1014] GAM82 gene, herein designated GAM GENE, and GAM82 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1015] GAM82 gene, herein designated GAM GENE, encodes a GAM82 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM82 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM82 precursor RNA is designated SEQ ID:1017, and is provided hereinbelow with reference

to the sequence listing part.

[1016] GAM82 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM82 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1017] An enzyme complex designated DICER COMPLEX, dices the GAM82 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM82 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM82 RNA is designated SEQ ID:1018, and is provided hereinbelow with reference to the sequence listing part.

[1018] GAM82 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM82 target RNA, herein designated GAM TARGET RNA. GAM82 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1019] GAM82 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM82 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM82 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM82 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM82 target RNA, herein designated GAM TARGET RNA. It is further

appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1020] The complementary binding of GAM82 RNA, herein designated GAM RNA, to target binding sites on GAM82 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM82 target RNA, herein designated GAM TARGET RNA, into GAM82 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1021] It is appreciated that GAM82 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM82 target genes. The mRNA of each one of this plurality of GAM82 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM82 RNA, herein designated GAM RNA, and which when bound by GAM82 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM82 target proteins.

[1022] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM82 gene, herein designated GAM GENE, on one or more GAM82 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1023] It is yet further appreciated that specific functions, and accordingly utilities, of GAM82 correlate with, and may be deduced from, the identity of the target genes which GAM82 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1024] Nucleotide sequences of the GAM82 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM82 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM82 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM82 are further described hereinbelow with reference to Table Table1.

[1025] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM82 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1026]

[1027] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 83 (GAM83) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1028] GAM83 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM83 was detected is described hereinabove with reference to Figs. 2-8.

[1029] GAM83 gene, herein designated GAM GENE, and GAM83 target gene, herein designated GAM TARGET GENE, are

human genes contained in the human genome.

[1030] GAM83 gene, herein designated GAM GENE, encodes a GAM83 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM83 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM83 precursor RNA is designated SEQ ID:1037, and is provided hereinbelow with reference to the sequence listing part.

[1031] GAM83 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM83 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1032] An enzyme complex designated DICER COMPLEX, dices the GAM83 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM83 RNA, herein desig-

nated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM83 RNA is designated SEQ ID:1038, and is provided hereinbelow with reference to the sequence listing part.

[1033] GAM83 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM83 target RNA, herein designated GAM TARGET RNA. GAM83 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1034] GAM83 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM83 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM83 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM83 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM83 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1035] The complementary binding of GAM83 RNA, herein designated GAM RNA, to target binding sites on GAM83 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM83 target RNA, herein designated GAM TARGET RNA, into GAM83 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1036] It is appreciated that GAM83 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM83 target genes. The mRNA of each one of this plurality of GAM83 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM83 RNA, herein designated GAM RNA, and which when bound by GAM83 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM83 target proteins.

[1037] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM83 gene, herein designated GAM GENE, on one or more GAM83 target gene, herein designated GAM TARGET

GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1038] It is yet further appreciated that specific functions, and accordingly utilities, of GAM83 correlate with, and may be deduced from, the identity of the target genes which GAM83 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1039] Nucleotide sequences of the GAM83 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM83 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM83 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM83 are further described hereinbelow with reference to Table Table1.

[1040] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM83 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1041]

[1042] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 84 (GAM84) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1043] GAM84 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM84 was detected is described hereinabove with reference to Figs. 2-8.

[1044] GAM84 gene, herein designated GAM GENE, and GAM84 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1045] GAM84 gene, herein designated GAM GENE, encodes a GAM84 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM84 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM84 precursor RNA is designated SEQ ID:1061, and is provided hereinbelow with reference to the sequence listing part.

[1046] GAM84 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM84 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1047] An enzyme complex designated DICER COMPLEX, dices the GAM84 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM84 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme

called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM84 RNA is designated SEQ ID:1062, and is provided hereinbelow with reference to the sequence listing part.

[1048] GAM84 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM84 target RNA, herein designated GAM TARGET RNA. GAM84 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1049] GAM84 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM84 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM84 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM84 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM84 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1050] The complementary binding of GAM84 RNA, herein designated GAM RNA, to target binding sites on GAM84 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM84 target RNA, herein designated GAM TARGET RNA, into GAM84 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1051] It is appreciated that GAM84 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM84 target genes. The mRNA of each one of this plurality of GAM84 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM84 RNA,

herein designated GAM RNA, and which when bound by GAM84 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM84 target proteins.

[1052] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM84 gene, herein designated GAM GENE, on one or more GAM84 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1053] It is yet further appreciated that specific functions, and accordingly utilities, of GAM84 correlate with, and may be deduced from, the identity of the target genes which

GAM84 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1054] Nucleotide sequences of the GAM84 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM84 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM84 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM84 are further described hereinbelow with reference to Table Table1.

[1055] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM84 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1056]

[1057] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 85 (GAM85) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1058] GAM85 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM85 was detected is described hereinabove with reference to Figs. 2-8.

[1059] GAM85 gene, herein designated GAM GENE, and GAM85 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1060] GAM85 gene, herein designated GAM GENE, encodes a GAM85 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM85 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM85 precursor RNA is designated SEQ ID:1078, and is provided hereinbelow with reference to the sequence listing part.

[1061] GAM85 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM85 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[1062] An enzyme complex designated DICER COMPLEX, dices the GAM85 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM85 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 18%) nucleotide sequence of GAM85 RNA is designated SEQ ID:1079, and is provided hereinbelow with reference to the sequence listing part.

[1063] GAM85 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM85 target RNA, herein designated GAM TARGET RNA. GAM85 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1064] GAM85 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM85 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM85 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM85 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM85 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1065] The complementary binding of GAM85 RNA, herein designated GAM RNA, to target binding sites on GAM85 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM85 target RNA, herein designated GAM

TARGET RNA, into GAM85 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1066] It is appreciated that GAM85 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM85 target genes. The mRNA of each one of this plurality of GAM85 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM85 RNA, herein designated GAM RNA, and which when bound by GAM85 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM85 target proteins.

[1067] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM85 gene, herein designated GAM GENE, on one or more GAM85 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other re-

cently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1068] It is yet further appreciated that specific functions, and accordingly utilities, of GAM85 correlate with, and may be deduced from, the identity of the target genes which GAM85 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1069] Nucleotide sequences of the GAM85 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM85 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM85 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM85 are further described hereinbelow with reference to Table Table1.

[1070] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM85 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[1071]

[1072] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 86 (GAM86) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1073] GAM86 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM86 was detected is described hereinabove with reference to Figs. 2-8.

[1074] GAM86 gene, herein designated GAM GENE, and GAM86 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1075] GAM86 gene, herein designated GAM GENE, encodes a GAM86 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM86 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM86 precursor RNA is designated SEQ ID:1095, and is provided hereinbelow with reference

to the sequence listing part.

[1076] GAM86 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM86 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1077] An enzyme complex designated DICER COMPLEX, dices the GAM86 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM86 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM86 RNA is designated SEQ ID:1096, and is provided hereinbelow with reference to the sequence listing part.

[1078] GAM86 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM86 target RNA, herein designated GAM TARGET RNA. GAM86 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1079] GAM86 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM86 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM86 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM86 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM86 target RNA, herein designated GAM TARGET RNA. It is further

appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1080] The complementary binding of GAM86 RNA, herein designated GAM RNA, to target binding sites on GAM86 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM86 target RNA, herein designated GAM TARGET RNA, into GAM86 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1081] It is appreciated that GAM86 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM86 target genes. The mRNA of each one of this plurality of GAM86 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM86 RNA, herein designated GAM RNA, and which when bound by GAM86 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM86 target proteins.

[1082] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM86 gene, herein designated GAM GENE, on one or more GAM86 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1083] It is yet further appreciated that specific functions, and accordingly utilities, of GAM86 correlate with, and may be deduced from, the identity of the target genes which GAM86 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1084] Nucleotide sequences of the GAM86 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM86 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM86 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM86 are further described hereinbelow with reference to Table Table1.

[1085] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM86 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1086]

[1087] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 87 (GAM87) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1088] GAM87 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM87 was detected is described hereinabove with reference to Figs. 2-8.

[1089] GAM87 gene, herein designated GAM GENE, and GAM87 target gene, herein designated GAM TARGET GENE, are

human genes contained in the human genome.

[1090] GAM87 gene, herein designated GAM GENE, encodes a GAM87 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM87 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM87 precursor RNA is designated SEQ ID:1111, and is provided hereinbelow with reference to the sequence listing part.

[1091] GAM87 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM87 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1092] An enzyme complex designated DICER COMPLEX, dices the GAM87 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM87 RNA, herein desig-

nated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM87 RNA is designated SEQ ID:1112, and is provided hereinbelow with reference to the sequence listing part.

[1093] GAM87 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM87 target RNA, herein designated GAM TARGET RNA. GAM87 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1094] GAM87 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM87 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM87 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM87 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM87 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1095] The complementary binding of GAM87 RNA, herein designated GAM RNA, to target binding sites on GAM87 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM87 target RNA, herein designated GAM TARGET RNA, into GAM87 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1096] It is appreciated that GAM87 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM87 target genes. The mRNA of each one of this plurality of GAM87 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM87 RNA, herein designated GAM RNA, and which when bound by GAM87 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM87 target proteins.

[1097] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM87 gene, herein designated GAM GENE, on one or more GAM87 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny

RNA world, Science 294,779 (2001)).

[1098] It is yet further appreciated that specific functions, and accordingly utilities, of GAM87 correlate with, and may be deduced from, the identity of the target genes which GAM87 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1099] Nucleotide sequences of the GAM87 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM87 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM87 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM87 are further described hereinbelow with reference to Table Table1.

[1100] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM87 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1101]

[1102] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

88 (GAM88) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1103] GAM88 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM88 was detected is described hereinabove with reference to Figs. 2-8.

[1104] GAM88 gene, herein designated GAM GENE, and GAM88 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1105] GAM88 gene, herein designated GAM GENE, encodes a GAM88 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM88 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM88 precursor RNA is designated SEQ ID:1124, and is provided hereinbelow with reference to the sequence listing part.

[1106] GAM88 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM88 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1107] An enzyme complex designated DICER COMPLEX, dices the GAM88 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM88 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM88 RNA is designated SEQ ID:1125, and is provided hereinbelow with reference to the sequence listing part.

[1108] GAM88 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM88 target RNA, herein designated GAM TARGET RNA. GAM88 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding re-

gion and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1109] GAM88 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM88 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM88 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM88 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM88 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1110] The complementary binding of GAM88 RNA, herein desig-

nated GAM RNA, to target binding sites on GAM88 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM88 target RNA, herein designated GAM TARGET RNA, into GAM88 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1111] It is appreciated that GAM88 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM88 target genes. The mRNA of each one of this plurality of GAM88 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM88 RNA, herein designated GAM RNA, and which when bound by GAM88 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM88 target proteins.

[1112] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM88 gene, herein designated GAM GENE, on one or more GAM88 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As

mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1113] It is yet further appreciated that specific functions, and accordingly utilities, of GAM88 correlate with, and may be deduced from, the identity of the target genes which GAM88 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1114] Nucleotide sequences of the GAM88 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM88 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM88 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM88 are further described hereinbelow with reference to Table Table1.

[1115] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM88 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1116]

[1117] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 89 (GAM89) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1118] GAM89 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM89 was detected is described hereinabove with reference to Figs. 2-8.

[1119] GAM89 gene, herein designated GAM GENE, and GAM89 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1120] GAM89 gene, herein designated GAM GENE, encodes a GAM89 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM89 precursor RNA, herein designated

GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM89 precursor RNA is designated SEQ ID:1140, and is provided hereinbelow with reference to the sequence listing part.

[1121] GAM89 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM89 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1122] An enzyme complex designated DICER COMPLEX, dices the GAM89 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM89 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A

probable (over 56%) nucleotide sequence of GAM89 RNA is designated SEQ ID:1141, and is provided hereinbelow with reference to the sequence listing part.

[1123] GAM89 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM89 target RNA, herein designated GAM TARGET RNA. GAM89 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1124] GAM89 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM89 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM89 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM89 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM89 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1125] The complementary binding of GAM89 RNA, herein designated GAM RNA, to target binding sites on GAM89 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM89 target RNA, herein designated GAM TARGET RNA, into GAM89 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1126] It is appreciated that GAM89 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM89 target genes. The mRNA of each one of this plurality of GAM89 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM89 RNA, herein designated GAM RNA, and which when bound by

GAM89 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM89 target proteins.

[1127] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM89 gene, herein designated GAM GENE, on one or more GAM89 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1128] It is yet further appreciated that specific functions, and accordingly utilities, of GAM89 correlate with, and may be deduced from, the identity of the target genes which GAM89 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[1129] Nucleotide sequences of the GAM89 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM89 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM89 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM89 are further described hereinbelow with reference to Table Table1.

[1130] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM89 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1131]

[1132] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 90 (GAM90) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1133] GAM90 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM90 was detected is described hereinabove with reference to Figs. 2-8.

[1134] GAM90 gene, herein designated GAM GENE, and GAM90 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1135] GAM90 gene, herein designated GAM GENE, encodes a GAM90 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM90 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM90 precursor RNA is designated SEQ ID:1159, and is provided hereinbelow with reference to the sequence listing part.

[1136] GAM90 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM90 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[1137] An enzyme complex designated DICER COMPLEX, dices the GAM90 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM90 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 82%) nucleotide sequence of GAM90 RNA is designated SEQ ID:1160, and is provided hereinbelow with reference to the sequence listing part.

[1138] GAM90 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM90 target RNA, herein designated GAM TARGET RNA. GAM90 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1139] GAM90 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM90 target RNA, herein desig-

nated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM90 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM90 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM90 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1140] The complementary binding of GAM90 RNA, herein designated GAM RNA, to target binding sites on GAM90 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM90 target RNA, herein designated GAM TARGET RNA, into GAM90 target protein, herein desig-

nated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1141] It is appreciated that GAM90 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM90 target genes. The mRNA of each one of this plurality of GAM90 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM90 RNA, herein designated GAM RNA, and which when bound by GAM90 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM90 target proteins.

[1142] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM90 gene, herein designated GAM GENE, on one or more GAM90 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those

skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1143] It is yet further appreciated that specific functions, and accordingly utilities, of GAM90 correlate with, and may be deduced from, the identity of the target genes which GAM90 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1144] Nucleotide sequences of the GAM90 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM90 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM90 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM90 are further described hereinbelow with reference to Table Table1.

[1145] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM90 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1146]

[1147] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 91 (GAM91) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1148] GAM91 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM91 was detected is described hereinabove with reference to Figs. 2-8.

[1149] GAM91 gene, herein designated GAM GENE, and GAM91 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1150] GAM91 gene, herein designated GAM GENE, encodes a GAM91 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM91 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM91 precursor RNA is designated SEQ ID:1168, and is provided hereinbelow with reference to the sequence listing part.

[1151] GAM91 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM91 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1152] An enzyme complex designated DICER COMPLEX, dices the GAM91 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM91 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM91 RNA is designated SEQ ID:1169, and is provided hereinbelow with reference to the sequence listing part.

[1153] GAM91 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM91

target RNA, herein designated GAM TARGET RNA. GAM91 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1154] GAM91 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM91 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM91 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM91 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM91 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites

in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1155] The complementary binding of GAM91 RNA, herein designated GAM RNA, to target binding sites on GAM91 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM91 target RNA, herein designated GAM TARGET RNA, into GAM91 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1156] It is appreciated that GAM91 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM91 target genes. The mRNA of each one of this plurality of GAM91 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM91 RNA, herein designated GAM RNA, and which when bound by GAM91 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM91 target proteins.

[1157] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM91 gene, herein designated GAM GENE, on one or more GAM91 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1158] It is yet further appreciated that specific functions, and accordingly utilities, of GAM91 correlate with, and may be deduced from, the identity of the target genes which GAM91 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1159] Nucleotide sequences of the GAM91 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM91 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM91 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM91 are further described hereinbelow with reference to Table Table1.

[1160] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM91 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1161]

[1162] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 92 (GAM92) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1163] GAM92 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM92 was detected is described hereinabove with reference to Figs. 2-8.

[1164] GAM92 gene, herein designated GAM GENE, and GAM92 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1165] GAM92 gene, herein designated GAM GENE, encodes a GAM92 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM92 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM92 precursor RNA is designated SEQ ID:1171, and is provided hereinbelow with reference to the sequence listing part.

[1166] GAM92 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM92 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1167] An enzyme complex designated DICER COMPLEX, dices the GAM92 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM92 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA seg-

ment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM92 RNA is designated SEQ ID:1172, and is provided hereinbelow with reference to the sequence listing part.

[1168] GAM92 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM92 target RNA, herein designated GAM TARGET RNA. GAM92 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1169] GAM92 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM92 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM92 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM92 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM92 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1170] The complementary binding of GAM92 RNA, herein designated GAM RNA, to target binding sites on GAM92 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM92 target RNA, herein designated GAM TARGET RNA, into GAM92 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1171] It is appreciated that GAM92 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM92 target genes. The mRNA of each one of this plu-

rality of GAM92 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM92 RNA, herein designated GAM RNA, and which when bound by GAM92 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM92 target proteins.

[1172] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM92 gene, herein designated GAM GENE, on one or more GAM92 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1173] It is yet further appreciated that specific functions, and accordingly utilities, of GAM92 correlate with, and may be deduced from, the identity of the target genes which GAM92 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1174] Nucleotide sequences of the GAM92 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM92 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM92 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM92 are further described hereinbelow with reference to Table Table1.

[1175] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM92 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1176]

[1177] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 93 (GAM93) gene, which modulates expression of respec-

tive target genes thereof, the function and utility of which target genes is known in the art.

[1178] GAM93 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM93 was detected is described hereinabove with reference to Figs. 2-8.

[1179] GAM93 gene, herein designated GAM GENE, and GAM93 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1180] GAM93 gene, herein designated GAM GENE, encodes a GAM93 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM93 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM93 precursor RNA is designated SEQ ID:1196, and is provided hereinbelow with reference to the sequence listing part.

[1181] GAM93 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM93 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1182] An enzyme complex designated DICER COMPLEX, dices the GAM93 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM93 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM93 RNA is designated SEQ ID:1197, and is provided hereinbelow with reference to the sequence listing part.

[1183] GAM93 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM93 target RNA, herein designated GAM TARGET RNA. GAM93 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PRO-

TEIN CODING and 3UTR respectively.

[1184] GAM93 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM93 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM93 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM93 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM93 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1185] The complementary binding of GAM93 RNA, herein designated GAM RNA, to target binding sites on GAM93 target

RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM93 target RNA, herein designated GAM TARGET RNA, into GAM93 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1186] It is appreciated that GAM93 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM93 target genes. The mRNA of each one of this plurality of GAM93 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM93 RNA, herein designated GAM RNA, and which when bound by GAM93 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM93 target proteins.

[1187] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM93 gene, herein designated GAM GENE, on one or more GAM93 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background

section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1188] It is yet further appreciated that specific functions, and accordingly utilities, of GAM93 correlate with, and may be deduced from, the identity of the target genes which GAM93 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1189] Nucleotide sequences of the GAM93 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM93 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM93 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM93 are further described hereinbelow with reference to Table Table1.

[1190] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM93 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1191]

[1192] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 94 (GAM94) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1193] GAM94 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM94 was detected is described hereinabove with reference to Figs. 2-8.

[1194] GAM94 gene, herein designated GAM GENE, and GAM94 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1195] GAM94 gene, herein designated GAM GENE, encodes a GAM94 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM94 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nu-

cleotide sequence identical or highly similar to the nucleotide sequence of GAM94 precursor RNA is designated SEQ ID:1206, and is provided hereinbelow with reference to the sequence listing part.

[1196] GAM94 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM94 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1197] An enzyme complex designated DICER COMPLEX, dices the GAM94 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM94 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 40%) nucleotide sequence of GAM94 RNA is

designated SEQ ID:1207, and is provided hereinbelow with reference to the sequence listing part.

[1198] GAM94 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM94 target RNA, herein designated GAM TARGET RNA. GAM94 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1199] GAM94 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM94 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM94 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM94 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM94 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1200] The complementary binding of GAM94 RNA, herein designated GAM RNA, to target binding sites on GAM94 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM94 target RNA, herein designated GAM TARGET RNA, into GAM94 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1201] It is appreciated that GAM94 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM94 target genes. The mRNA of each one of this plurality of GAM94 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM94 RNA, herein designated GAM RNA, and which when bound by GAM94 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM94 target proteins.

[1202] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM94 gene, herein designated GAM GENE, on one or more GAM94 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1203] It is yet further appreciated that specific functions, and accordingly utilities, of GAM94 correlate with, and may be deduced from, the identity of the target genes which GAM94 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1204] Nucleotide sequences of the GAM94 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM94 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM94 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM94 are further described hereinbelow with reference to Table Table1.

[1205] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM94 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1206]

[1207] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 95 (GAM95) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1208] GAM95 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM95 was detected is described hereinabove

with reference to Figs. 2-8.

[1209] GAM95 gene, herein designated GAM GENE, and GAM95 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1210] GAM95 gene, herein designated GAM GENE, encodes a GAM95 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM95 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM95 precursor RNA is designated SEQ ID:1220, and is provided hereinbelow with reference to the sequence listing part.

[1211] GAM95 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM95 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1212] An enzyme complex designated DICER COMPLEX, dices the GAM95 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM95 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 37%) nucleotide sequence of GAM95 RNA is designated SEQ ID:1221, and is provided hereinbelow with reference to the sequence listing part.

[1213] GAM95 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM95 target RNA, herein designated GAM TARGET RNA. GAM95 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1214] GAM95 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM95 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM95 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM95 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM95 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1215] The complementary binding of GAM95 RNA, herein designated GAM RNA, to target binding sites on GAM95 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM95 target RNA, herein designated GAM TARGET RNA, into GAM95 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is there-

fore outlined by a broken line.

[1216] It is appreciated that GAM95 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM95 target genes. The mRNA of each one of this plurality of GAM95 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM95 RNA, herein designated GAM RNA, and which when bound by GAM95 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM95 target proteins.

[1217] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM95 gene, herein designated GAM GENE, on one or more GAM95 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes

by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1218] It is yet further appreciated that specific functions, and accordingly utilities, of GAM95 correlate with, and may be deduced from, the identity of the target genes which GAM95 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1219] Nucleotide sequences of the GAM95 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM95 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM95 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM95 are further described hereinbelow with reference to Table Table1.

[1220] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM95 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1221]

[1222] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 96 (GAM96) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1223] GAM96 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM96 was detected is described hereinabove with reference to Figs. 2-8.

[1224] GAM96 gene, herein designated GAM GENE, and GAM96 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1225] GAM96 gene, herein designated GAM GENE, encodes a GAM96 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM96 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM96 precursor RNA is designated SEQ ID:1227, and is provided hereinbelow with reference to the sequence listing part.

[1226] GAM96 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM96 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1227] An enzyme complex designated DICER COMPLEX, dices the GAM96 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM96 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 34%) nucleotide sequence of GAM96 RNA is designated SEQ ID:1228, and is provided hereinbelow with reference to the sequence listing part.

[1228] GAM96 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM96 target RNA, herein designated GAM TARGET RNA. GAM96

target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1229] GAM96 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM96 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM96 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM96 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM96 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1230] The complementary binding of GAM96 RNA, herein designated GAM RNA, to target binding sites on GAM96 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM96 target RNA, herein designated GAM TARGET RNA, into GAM96 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1231] It is appreciated that GAM96 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM96 target genes. The mRNA of each one of this plurality of GAM96 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM96 RNA, herein designated GAM RNA, and which when bound by GAM96 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM96 target proteins.

[1232] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM96 gene, herein designated GAM GENE, on one or more GAM96 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1233] It is yet further appreciated that specific functions, and accordingly utilities, of GAM96 correlate with, and may be deduced from, the identity of the target genes which GAM96 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1234] Nucleotide sequences of the GAM96 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM96 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM96 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM96 are further described hereinbelow with reference to Table Table1.

[1235] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM96 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1236]

[1237] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 97 (GAM97) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1238] GAM97 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM97 was detected is described hereinabove with reference to Figs. 2-8.

[1239] GAM97 gene, herein designated GAM GENE, and GAM97 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1240] GAM97 gene, herein designated GAM GENE, encodes a

GAM97 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM97 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM97 precursor RNA is designated SEQ ID:1259, and is provided hereinbelow with reference to the sequence listing part.

[1241] GAM97 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM97 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1242] An enzyme complex designated DICER COMPLEX, dices the GAM97 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM97 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured

RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 18%) nucleotide sequence of GAM97 RNA is designated SEQ ID:1260, and is provided hereinbelow with reference to the sequence listing part.

[1243] GAM97 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM97 target RNA, herein designated GAM TARGET RNA. GAM97 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1244] GAM97 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM97 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM97 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM97 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM97 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1245] The complementary binding of GAM97 RNA, herein designated GAM RNA, to target binding sites on GAM97 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM97 target RNA, herein designated GAM TARGET RNA, into GAM97 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1246] It is appreciated that GAM97 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM97 target genes. The mRNA of each one of this plurality of GAM97 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM97 RNA, herein designated GAM RNA, and which when bound by GAM97 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM97 target proteins.

[1247] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM97 gene, herein designated GAM GENE, on one or more GAM97 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1248] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM97 correlate with, and may be deduced from, the identity of the target genes which GAM97 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1249] Nucleotide sequences of the GAM97 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM97 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM97 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM97 are further described hereinbelow with reference to Table Table1.

[1250] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM97 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1251]

[1252] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 98 (GAM98) gene, which modulates expression of respective target genes thereof, the function and utility of which

target genes is known in the art.

[1253] GAM98 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM98 was detected is described hereinabove with reference to Figs. 2-8.

[1254] GAM98 gene, herein designated GAM GENE, and GAM98 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1255] GAM98 gene, herein designated GAM GENE, encodes a GAM98 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM98 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM98 precursor RNA is designated SEQ ID:1276, and is provided hereinbelow with reference to the sequence listing part.

[1256] GAM98 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM98 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1257] An enzyme complex designated DICER COMPLEX, dices the GAM98 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM98 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 30%) nucleotide sequence of GAM98 RNA is designated SEQ ID:1277, and is provided hereinbelow with reference to the sequence listing part.

[1258] GAM98 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM98 target RNA, herein designated GAM TARGET RNA. GAM98 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1259] GAM98 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM98 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM98 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM98 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM98 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1260] The complementary binding of GAM98 RNA, herein designated GAM RNA, to target binding sites on GAM98 target RNA, herein designated GAM TARGET RNA, such as BIND-

ING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM98 target RNA, herein designated GAM TARGET RNA, into GAM98 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1261] It is appreciated that GAM98 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM98 target genes. The mRNA of each one of this plurality of GAM98 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM98 RNA, herein designated GAM RNA, and which when bound by GAM98 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM98 target proteins.

[1262] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM98 gene, herein designated GAM GENE, on one or more GAM98 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site

has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1263] It is yet further appreciated that specific functions, and accordingly utilities, of GAM98 correlate with, and may be deduced from, the identity of the target genes which GAM98 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1264] Nucleotide sequences of the GAM98 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM98 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM98 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM98 are further described hereinbelow with reference to Table Table1.

[1265] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM98 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1266]

[1267] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 99 (GAM99) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1268] GAM99 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM99 was detected is described hereinabove with reference to Figs. 2-8.

[1269] GAM99 gene, herein designated GAM GENE, and GAM99 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1270] GAM99 gene, herein designated GAM GENE, encodes a GAM99 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM99 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM99 precursor RNA is designated SEQ ID:1293, and is provided hereinbelow with reference to the sequence listing part.

[1271] GAM99 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM99 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1272] An enzyme complex designated DICER COMPLEX, dices the GAM99 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM99 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 35%) nucleotide sequence of GAM99 RNA is designated SEQ ID:1294, and is provided hereinbelow with

reference to the sequence listing part.

[1273] GAM99 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM99 target RNA, herein designated GAM TARGET RNA. GAM99 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1274] GAM99 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM99 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM99 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM99 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM99 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1275] The complementary binding of GAM99 RNA, herein designated GAM RNA, to target binding sites on GAM99 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM99 target RNA, herein designated GAM TARGET RNA, into GAM99 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1276] It is appreciated that GAM99 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM99 target genes. The mRNA of each one of this plurality of GAM99 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM99 RNA, herein designated GAM RNA, and which when bound by GAM99 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM99 tar-

get proteins.

[1277] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM99 gene, herein designated GAM GENE, on one or more GAM99 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1278] It is yet further appreciated that specific functions, and accordingly utilities, of GAM99 correlate with, and may be deduced from, the identity of the target genes which GAM99 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1279] Nucleotide sequences of the GAM99 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM99 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM99 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM99 are further described hereinbelow with reference to Table Table1.

[1280] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM99 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1281]

[1282] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 100 (GAM100) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1283] GAM100 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM100 was detected is described hereinabove with reference to Figs. 2-8.

[1284] GAM100 gene, herein designated GAM GENE, and GAM100 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1285] GAM100 gene, herein designated GAM GENE, encodes a GAM100 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM100 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM100 precursor RNA is designated SEQ ID:1303, and is provided hereinbelow with reference to the sequence listing part.

[1286] GAM100 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM100 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1287] An enzyme complex designated DICER COMPLEX, dices

the GAM100 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM100 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM100 RNA is designated SEQ ID:1304, and is provided hereinbelow with reference to the sequence listing part.

[1288] GAM100 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM100 target RNA, herein designated GAM TARGET RNA.

GAM100 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1289] GAM100 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM100 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM100

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM100 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM100 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1290] The complementary binding of GAM100 RNA, herein designated GAM RNA, to target binding sites on GAM100 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM100 target RNA, herein designated GAM TARGET RNA, into GAM100 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1291] It is appreciated that GAM100 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM100 target genes. The mRNA of each one of this plurality of GAM100 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM100 RNA, herein designated GAM RNA, and which when bound by GAM100 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM100 target proteins.

[1292] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM100 gene, herein designated GAM GENE, on one or more GAM100 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1293] It is yet further appreciated that specific functions, and accordingly utilities, of GAM100 correlate with, and may be deduced from, the identity of the target genes which GAM100 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1294] Nucleotide sequences of the GAM100 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM100 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM100 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM100 are further described hereinbelow with reference to Table Table1.

[1295] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM100 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1296]

[1297] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 101 (GAM101) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1298] GAM101 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM101 was detected is described hereinabove with reference to Figs. 2-8.

[1299] GAM101 gene, herein designated GAM GENE, and GAM101 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1300] GAM101 gene, herein designated GAM GENE, encodes a GAM101 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM101 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM101 precursor RNA is designated SEQ ID:1315, and is provided hereinbelow with reference to the sequence listing part.

[1301] GAM101 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM101 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1302] An enzyme complex designated DICER COMPLEX, dices the GAM101 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM101 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM101 RNA is designated SEQ ID:1316, and is provided hereinbelow with reference to the sequence listing part.

[1303] GAM101 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM101 target RNA, herein designated GAM TARGET RNA. GAM101 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1304] GAM101 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM101 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM101 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM101 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM101 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[1305] The complementary binding of GAM101 RNA, herein designated GAM RNA, to target binding sites on GAM101 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM101 target RNA, herein designated GAM TARGET RNA, into GAM101 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1306] It is appreciated that GAM101 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM101 target genes. The mRNA of each one of this plurality of GAM101 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM101 RNA, herein designated GAM RNA, and which when bound by GAM101 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM101 target proteins.

[1307] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM101 gene, herein designated GAM GENE, on one or

more GAM101 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1308] It is yet further appreciated that specific functions, and accordingly utilities, of GAM101 correlate with, and may be deduced from, the identity of the target genes which GAM101 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1309] Nucleotide sequences of the GAM101 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM101 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM101 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM101 are further de-

scribed hereinbelow with reference to Table Table1.

[1310] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM101 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1311]

[1312] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 102 (GAM102) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1313] GAM102 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM102 was detected is described hereinabove with reference to Figs. 2-8.

[1314] GAM102 gene, herein designated GAM GENE, and GAM102 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1315] GAM102 gene, herein designated GAM GENE, encodes a GAM102 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM102 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM102 precursor RNA is designated SEQ ID:1330, and is provided hereinbelow with reference to the sequence listing part.

[1316] GAM102 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM102 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1317] An enzyme complex designated DICER COMPLEX, dices the GAM102 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM102 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM102 RNA is designated SEQ ID:1316, and is provided hereinbelow with reference to the sequence listing part.

[1318] GAM102 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM102 target RNA, herein designated GAM TARGET RNA. GAM102 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1319] GAM102 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM102 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM102 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM102 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM102 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1320] The complementary binding of GAM102 RNA, herein designated GAM RNA, to target binding sites on GAM102 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM102 target RNA, herein designated GAM TARGET RNA, into GAM102 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1321] It is appreciated that GAM102 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM102 target genes. The mRNA of each one of this plurality of GAM102 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM102 RNA, herein designated GAM RNA, and which when bound by GAM102 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM102 target proteins.

[1322] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM102 gene, herein designated GAM GENE, on one or more GAM102 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1323] It is yet further appreciated that specific functions, and accordingly utilities, of GAM102 correlate with, and may

be deduced from, the identity of the target genes which GAM102 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1324] Nucleotide sequences of the GAM102 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM102 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM102 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM102 are further described hereinbelow with reference to Table Table1.

[1325] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM102 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1326]

[1327] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 103 (GAM103) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1328] GAM103 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM103 was detected is described hereinabove with reference to Figs. 2-8.

[1329] GAM103 gene, herein designated GAM GENE, and GAM103 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1330] GAM103 gene, herein designated GAM GENE, encodes a GAM103 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM103 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM103 precursor RNA is designated SEQ ID:1336, and is provided hereinbelow with reference to the sequence listing part.

[1331] GAM103 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM103 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1332] An enzyme complex designated DICER COMPLEX, dices the GAM103 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM103 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM103 RNA is designated SEQ ID:1337, and is provided hereinbelow with reference to the sequence listing part.

[1333] GAM103 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM103 target RNA, herein designated GAM TARGET RNA. GAM103 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1334] GAM103 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM103 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM103 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM103 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM103 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1335] The complementary binding of GAM103 RNA, herein designated GAM RNA, to target binding sites on GAM103 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM103 target RNA, herein designated GAM TARGET RNA, into GAM103 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1336] It is appreciated that GAM103 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM103 target genes. The mRNA of each one of this plurality of GAM103 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM103 RNA, herein designated GAM RNA, and which when bound by GAM103 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM103 target proteins.

[1337] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM103 gene, herein designated GAM GENE, on one or more GAM103 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1338] It is yet further appreciated that specific functions, and accordingly utilities, of GAM103 correlate with, and may be deduced from, the identity of the target genes which GAM103 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1339] Nucleotide sequences of the GAM103 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM103 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM103 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM103 are further described hereinbelow with reference to Table Table1.

[1340] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM103 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1341]

[1342] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 104 (GAM104) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1343] GAM104 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM104 was detected is described hereinabove with reference to Figs. 2-8.

[1344] GAM104 gene, herein designated GAM GENE, and GAM104 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1345] GAM104 gene, herein designated GAM GENE, encodes a GAM104 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM104 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM104 precursor RNA is desig-

nated SEQ ID:1347, and is provided hereinbelow with reference to the sequence listing part.

[1346] GAM104 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM104 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1347] An enzyme complex designated DICER COMPLEX, dices the GAM104 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM104 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 31%) nucleotide sequence of GAM104 RNA is designated SEQ ID:1348, and is provided hereinbelow with reference to the sequence listing part.

[1348] GAM104 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM104 target RNA, herein designated GAM TARGET RNA. GAM104 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1349] GAM104 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM104 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM104 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM104 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM104

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1350] The complementary binding of GAM104 RNA, herein designated GAM RNA, to target binding sites on GAM104 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM104 target RNA, herein designated GAM TARGET RNA, into GAM104 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1351] It is appreciated that GAM104 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM104 target genes. The mRNA of each one of this plurality of GAM104 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM104 RNA, herein designated GAM RNA, and which when bound by GAM104 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM104 target proteins.

[1352] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM104 gene, herein designated GAM GENE, on one or more GAM104 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1353] It is yet further appreciated that specific functions, and accordingly utilities, of GAM104 correlate with, and may be deduced from, the identity of the target genes which GAM104 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1354] Nucleotide sequences of the GAM104 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM104 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM104 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM104 are further described hereinbelow with reference to Table Table1.

[1355] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM104 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1356]

[1357] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 105 (GAM105) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1358] GAM105 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM105 was detected is described hereinabove with reference to Figs. 2-8.

[1359] GAM105 gene, herein designated GAM GENE, and

GAM105 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1360] GAM105 gene, herein designated GAM GENE, encodes a GAM105 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM105 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM105 precursor RNA is designated SEQ ID:1391, and is provided hereinbelow with reference to the sequence listing part.

[1361] GAM105 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM105 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1362] An enzyme complex designated DICER COMPLEX, dices the GAM105 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM105 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM105 RNA is designated SEQ ID:1392, and is provided hereinbelow with reference to the sequence listing part.

[1363] GAM105 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM105 target RNA, herein designated GAM TARGET RNA. GAM105 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1364] GAM105 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM105 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM105 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM105 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM105 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1365] The complementary binding of GAM105 RNA, herein designated GAM RNA, to target binding sites on GAM105 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM105 target RNA, herein designated GAM TARGET RNA, into GAM105 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1366] It is appreciated that GAM105 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM105 target genes. The mRNA of each one of this plurality of GAM105 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM105 RNA, herein designated GAM RNA, and which when bound by GAM105 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM105 target proteins.

[1367] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM105 gene, herein designated GAM GENE, on one or more GAM105 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1368] It is yet further appreciated that specific functions, and accordingly utilities, of GAM105 correlate with, and may be deduced from, the identity of the target genes which GAM105 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1369] Nucleotide sequences of the GAM105 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM105 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM105 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM105 are further described hereinbelow with reference to Table Table1.

[1370] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM105 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1371]

[1372] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 106 (GAM106) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1373] GAM106 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM106 was detected is described hereinabove with reference to Figs. 2-8.

[1374] GAM106 gene, herein designated GAM GENE, and GAM106 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1375] GAM106 gene, herein designated GAM GENE, encodes a GAM106 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM106 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM106 precursor RNA is designated SEQ ID:1403, and is provided hereinbelow with reference to the sequence listing part.

[1376] GAM106 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM106 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1377] An enzyme complex designated DICER COMPLEX, dices the GAM106 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM106 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM106 RNA is designated SEQ ID:1404, and is provided hereinbelow with reference to the sequence listing part.

[1378] GAM106 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM106 target RNA, herein designated GAM TARGET RNA. GAM106 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1379] GAM106 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM106 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM106 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM106 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM106 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1380] The complementary binding of GAM106 RNA, herein designated GAM RNA, to target binding sites on GAM106 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM106 target RNA, herein designated GAM TARGET RNA, into GAM106 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1381] It is appreciated that GAM106 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM106 target genes. The mRNA of each one of this plurality of GAM106 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM106 RNA, herein designated GAM RNA, and which when bound by GAM106 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM106 target proteins.

[1382] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM106 gene, herein designated GAM GENE, on one or more GAM106 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1383] It is yet further appreciated that specific functions, and accordingly utilities, of GAM106 correlate with, and may be deduced from, the identity of the target genes which GAM106 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1384] Nucleotide sequences of the GAM106 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM106 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM106 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM106 are further described hereinbelow with reference to Table Table1.

[1385] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM106 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1386]

[1387] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 107 (GAM107) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1388] GAM107 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM107 was detected is described hereinabove with reference to Figs. 2-8.

[1389] GAM107 gene, herein designated GAM GENE, and GAM107 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1390] GAM107 gene, herein designated GAM GENE, encodes a GAM107 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM107 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM107 precursor RNA is designated SEQ ID:1411, and is provided hereinbelow with reference to the sequence listing part.

[1391] GAM107 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM107 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1392] An enzyme complex designated DICER COMPLEX, dices the GAM107 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM107 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 34%) nucleotide sequence of GAM107 RNA is designated SEQ ID:1412, and is provided hereinbelow with reference to the sequence listing part.

[1393] GAM107 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM107 target RNA, herein designated GAM TARGET RNA. GAM107 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1394] GAM107 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM107 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM107 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM107 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM107 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1395] The complementary binding of GAM107 RNA, herein designated GAM RNA, to target binding sites on GAM107 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM107 target RNA, herein designated GAM TARGET RNA, into GAM107 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1396] It is appreciated that GAM107 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM107 target genes. The mRNA of each one of this plurality of GAM107 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM107 RNA,

herein designated GAM RNA, and which when bound by GAM107 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM107 target proteins.

[1397] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM107 gene, herein designated GAM GENE, on one or more GAM107 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1398] It is yet further appreciated that specific functions, and accordingly utilities, of GAM107 correlate with, and may be deduced from, the identity of the target genes which

GAM107 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1399] Nucleotide sequences of the GAM107 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM107 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM107 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM107 are further described hereinbelow with reference to Table Table1.

[1400] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM107 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1401]

[1402] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 108 (GAM108) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1403] GAM108 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM108 was detected is described hereinabove with reference to Figs. 2-8.

[1404] GAM108 gene, herein designated GAM GENE, and GAM108 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1405] GAM108 gene, herein designated GAM GENE, encodes a GAM108 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM108 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM108 precursor RNA is designated SEQ ID:1428, and is provided hereinbelow with reference to the sequence listing part.

[1406] GAM108 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM108 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[1407] An enzyme complex designated DICER COMPLEX, dices the GAM108 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM108 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM108 RNA is designated SEQ ID:1429, and is provided hereinbelow with reference to the sequence listing part.

[1408] GAM108 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM108 target RNA, herein designated GAM TARGET RNA.
GAM108 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1409] GAM108 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM108 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM108 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM108 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM108 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1410] The complementary binding of GAM108 RNA, herein designated GAM RNA, to target binding sites on GAM108 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM108 target RNA, herein desig-

nated GAM TARGET RNA, into GAM108 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1411] It is appreciated that GAM108 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM108 target genes. The mRNA of each one of this plurality of GAM108 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM108 RNA, herein designated GAM RNA, and which when bound by GAM108 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM108 target proteins.

[1412] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM108 gene, herein designated GAM GENE, on one or more GAM108 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1413] It is yet further appreciated that specific functions, and accordingly utilities, of GAM108 correlate with, and may be deduced from, the identity of the target genes which GAM108 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1414] Nucleotide sequences of the GAM108 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM108 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM108 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM108 are further described hereinbelow with reference to Table Table1.

[1415] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM108 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[1416]

[1417] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 109 (GAM109) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1418] GAM109 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM109 was detected is described hereinabove with reference to Figs. 2-8.

[1419] GAM109 gene, herein designated GAM GENE, and GAM109 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1420] GAM109 gene, herein designated GAM GENE, encodes a GAM109 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM109 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM109 precursor RNA is designated SEQ ID:1443, and is provided hereinbelow with ref-

erence to the sequence listing part.

[1421] GAM109 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM109 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1422] An enzyme complex designated DICER COMPLEX, dices the GAM109 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM109 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 29%) nucleotide sequence of GAM109 RNA is designated SEQ ID:1444, and is provided hereinbelow with reference to the sequence listing part.

[1423] GAM109 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM109 target RNA, herein designated GAM TARGET RNA.

GAM109 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1424] GAM109 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM109 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM109 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM109 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM109 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1425] The complementary binding of GAM109 RNA, herein designated GAM RNA, to target binding sites on GAM109 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM109 target RNA, herein designated GAM TARGET RNA, into GAM109 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1426] It is appreciated that GAM109 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM109 target genes. The mRNA of each one of this plurality of GAM109 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM109 RNA, herein designated GAM RNA, and which when bound by GAM109 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM109 target proteins.

[1427] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM109 gene, herein designated GAM GENE, on one or more GAM109 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1428] It is yet further appreciated that specific functions, and accordingly utilities, of GAM109 correlate with, and may be deduced from, the identity of the target genes which GAM109 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1429] Nucleotide sequences of the GAM109 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM109 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM109 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM109 are further described hereinbelow with reference to Table Table1.

[1430] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM109 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1431]

[1432] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 110 (GAM110) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1433] GAM110 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM110 was detected is described hereinabove with reference to Figs. 2-8.

[1434] GAM110 gene, herein designated GAM GENE, and GAM110 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[1435] GAM110 gene, herein designated GAM GENE, encodes a GAM110 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM110 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM110 precursor RNA is designated SEQ ID:1462, and is provided hereinbelow with reference to the sequence listing part.

[1436] GAM110 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM110 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1437] An enzyme complex designated DICER COMPLEX, dices the GAM110 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM110 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM110 RNA is designated SEQ ID:1463, and is provided hereinbelow with reference to the sequence listing part.

[1438] GAM110 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM110 target RNA, herein designated GAM TARGET RNA. GAM110 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1439] GAM110 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM110 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM110 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM110 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM110 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1440] The complementary binding of GAM110 RNA, herein designated GAM RNA, to target binding sites on GAM110 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM110 target RNA, herein designated GAM TARGET RNA, into GAM110 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1441] It is appreciated that GAM110 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM110 target genes. The mRNA of each one of this plurality of GAM110 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM110 RNA, herein designated GAM RNA, and which when bound by GAM110 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM110 target proteins.

[1442] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM110 gene, herein designated GAM GENE, on one or more GAM110 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[1443] It is yet further appreciated that specific functions, and accordingly utilities, of GAM110 correlate with, and may be deduced from, the identity of the target genes which GAM110 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1444] Nucleotide sequences of the GAM110 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM110 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM110 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM110 are further described hereinbelow with reference to Table Table1.

[1445] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM110 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1446]

[1447] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

111 (GAM111) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1448] GAM111 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM111 was detected is described hereinabove with reference to Figs. 2-8.

[1449] GAM111 gene, herein designated GAM GENE, and GAM111 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1450] GAM111 gene, herein designated GAM GENE, encodes a GAM111 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM111 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM111 precursor RNA is designated SEQ ID:1487, and is provided hereinbelow with reference to the sequence listing part.

[1451] GAM111 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM111 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1452] An enzyme complex designated DICER COMPLEX, dices the GAM111 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM111 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM111 RNA is designated SEQ ID:1488, and is provided hereinbelow with reference to the sequence listing part.

[1453] GAM111 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM111 target RNA, herein designated GAM TARGET RNA. GAM111 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1454] GAM111 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM111 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM111 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM111 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM111 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1455] The complementary binding of GAM111 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM111 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM111 target RNA, herein designated GAM TARGET RNA, into GAM111 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1456] It is appreciated that GAM111 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM111 target genes. The mRNA of each one of this plurality of GAM111 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM111 RNA, herein designated GAM RNA, and which when bound by GAM111 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM111 target proteins.

[1457] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM111 gene, herein designated GAM GENE, on one or more GAM111 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1458] It is yet further appreciated that specific functions, and accordingly utilities, of GAM111 correlate with, and may be deduced from, the identity of the target genes which GAM111 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1459] Nucleotide sequences of the GAM111 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM111 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM111 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM111 are further described hereinbelow with reference to Table Table1.

[1460] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM111 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1461]

[1462] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 112 (GAM112) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1463] GAM112 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM112 was detected is described hereinabove with reference to Figs. 2-8.

[1464] GAM112 gene, herein designated GAM GENE, and GAM112 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1465] GAM112 gene, herein designated GAM GENE, encodes a GAM112 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM112 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM112 precursor RNA is designated SEQ ID:1494, and is provided hereinbelow with reference to the sequence listing part.

[1466] GAM112 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM112 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1467] An enzyme complex designated DICER COMPLEX, dices the GAM112 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM112 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 59%) nucleotide sequence of GAM112 RNA is designated SEQ ID:1495, and is provided hereinbelow with reference to the sequence listing part.

[1468] GAM112 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM112 target RNA, herein designated GAM TARGET RNA. GAM112 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1469] GAM112 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM112 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM112 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM112 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM112 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1470] The complementary binding of GAM112 RNA, herein designated GAM RNA, to target binding sites on GAM112 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM112 target RNA, herein designated GAM TARGET RNA, into GAM112 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1471] It is appreciated that GAM112 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM112 target genes. The mRNA of each one of this plurality of GAM112 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM112 RNA, herein designated GAM RNA, and which when bound by

GAM112 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM112 target proteins.

[1472] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM112 gene, herein designated GAM GENE, on one or more GAM112 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1473] It is yet further appreciated that specific functions, and accordingly utilities, of GAM112 correlate with, and may be deduced from, the identity of the target genes which GAM112 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[1474] Nucleotide sequences of the GAM112 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM112 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM112 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM112 are further described hereinbelow with reference to Table Table1.

[1475] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM112 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1476]

[1477] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 113 (GAM113) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1478] GAM113 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM113 was detected is described hereinabove with reference to Figs. 2-8.

[1479] GAM113 gene, herein designated GAM GENE, and GAM113 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1480] GAM113 gene, herein designated GAM GENE, encodes a GAM113 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM113 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM113 precursor RNA is designated SEQ ID:1515, and is provided hereinbelow with reference to the sequence listing part.

[1481] GAM113 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM113 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[1482] An enzyme complex designated DICER COMPLEX, dices the GAM113 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM113 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM113 RNA is designated SEQ ID:1516, and is provided hereinbelow with reference to the sequence listing part.

[1483] GAM113 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM113 target RNA, herein designated GAM TARGET RNA. GAM113 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1484] GAM113 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM113 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM113 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM113 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM113 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1485] The complementary binding of GAM113 RNA, herein designated GAM RNA, to target binding sites on GAM113 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM113 target RNA, herein designated GAM TARGET RNA, into GAM113 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1486] It is appreciated that GAM113 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM113 target genes. The mRNA of each one of this plurality of GAM113 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM113 RNA, herein designated GAM RNA, and which when bound by GAM113 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM113 target proteins.

[1487] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM113 gene, herein designated GAM GENE, on one or more GAM113 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1488] It is yet further appreciated that specific functions, and accordingly utilities, of GAM113 correlate with, and may be deduced from, the identity of the target genes which GAM113 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1489] Nucleotide sequences of the GAM113 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM113 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM113 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM113 are further described hereinbelow with reference to Table Table1.

[1490] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM113 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1491]

[1492] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 114 (GAM114) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1493] GAM114 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM114 was detected is described hereinabove with reference to Figs. 2-8.

[1494] GAM114 gene, herein designated GAM GENE, and GAM114 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1495] GAM114 gene, herein designated GAM GENE, encodes a GAM114 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM114 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM114 precursor RNA is designated SEQ ID:1525, and is provided hereinbelow with reference to the sequence listing part.

[1496] GAM114 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM114 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1497] An enzyme complex designated DICER COMPLEX, dices the GAM114 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM114 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM114 RNA is designated SEQ ID:1526, and is provided hereinbelow with reference to the sequence listing part.

[1498] GAM114 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM114

target RNA, herein designated GAM TARGET RNA.

GAM114 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1499] GAM114 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM114 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM114 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM114 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM114 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1500] The complementary binding of GAM114 RNA, herein designated GAM RNA, to target binding sites on GAM114 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM114 target RNA, herein designated GAM TARGET RNA, into GAM114 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1501] It is appreciated that GAM114 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM114 target genes. The mRNA of each one of this plurality of GAM114 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM114 RNA, herein designated GAM RNA, and which when bound by GAM114 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM114 target proteins.

[1502] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM114 gene, herein designated GAM GENE, on one or more GAM114 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1503] It is yet further appreciated that specific functions, and accordingly utilities, of GAM114 correlate with, and may be deduced from, the identity of the target genes which GAM114 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1504] Nucleotide sequences of the GAM114 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM114 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM114 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM114 are further described hereinbelow with reference to Table Table1.

[1505] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM114 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1506]

[1507] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 115 (GAM115) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1508] GAM115 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM115 was detected is described hereinabove with reference to Figs. 2-8.

[1509] GAM115 gene, herein designated GAM GENE, and GAM115 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1510] GAM115 gene, herein designated GAM GENE, encodes a GAM115 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM115 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM115 precursor RNA is designated SEQ ID:1575, and is provided hereinbelow with reference to the sequence listing part.

[1511] GAM115 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM115 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1512] An enzyme complex designated DICER COMPLEX, dices the GAM115 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM115 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM115 RNA is designated SEQ ID:1576, and is provided hereinbelow with reference to the sequence listing part.

[1513] GAM115 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM115 target RNA, herein designated GAM TARGET RNA. GAM115 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1514] GAM115 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM115 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM115 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM115 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM115 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1515] The complementary binding of GAM115 RNA, herein designated GAM RNA, to target binding sites on GAM115 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM115 target RNA, herein designated GAM TARGET RNA, into GAM115 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1516] It is appreciated that GAM115 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM115 target genes. The mRNA of each one of this plu-

rality of GAM115 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM115 RNA, herein designated GAM RNA, and which when bound by GAM115 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM115 target proteins.

[1517] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM115 gene, herein designated GAM GENE, on one or more GAM115 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1518] It is yet further appreciated that specific functions, and accordingly utilities, of GAM115 correlate with, and may be deduced from, the identity of the target genes which GAM115 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1519] Nucleotide sequences of the GAM115 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM115 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM115 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM115 are further described hereinbelow with reference to Table Table1.

[1520] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM115 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1521]

[1522] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 116 (GAM116) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[1523] GAM116 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM116 was detected is described hereinabove with reference to Figs. 2-8.

[1524] GAM116 gene, herein designated GAM GENE, and GAM116 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1525] GAM116 gene, herein designated GAM GENE, encodes a GAM116 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM116 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM116 precursor RNA is designated SEQ ID:1589, and is provided hereinbelow with reference to the sequence listing part.

[1526] GAM116 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM116 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1527] An enzyme complex designated DICER COMPLEX, dices the GAM116 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM116 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM116 RNA is designated SEQ ID:1590, and is provided hereinbelow with reference to the sequence listing part.

[1528] GAM116 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM116 target RNA, herein designated GAM TARGET RNA.

GAM116 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[1529] GAM116 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM116 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM116 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM116 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM116 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1530] The complementary binding of GAM116 RNA, herein designated GAM RNA, to target binding sites on GAM116 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM116 target RNA, herein designated GAM TARGET RNA, into GAM116 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1531] It is appreciated that GAM116 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM116 target genes. The mRNA of each one of this plurality of GAM116 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM116 RNA, herein designated GAM RNA, and which when bound by GAM116 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM116 target proteins.

[1532] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM116 gene, herein designated GAM GENE, on one or more GAM116 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1533] It is yet further appreciated that specific functions, and accordingly utilities, of GAM116 correlate with, and may be deduced from, the identity of the target genes which GAM116 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1534] Nucleotide sequences of the GAM116 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM116 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM116 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM116 are further described hereinbelow with reference to Table Table1.

[1535] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM116 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1536]

[1537] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 117 (GAM117) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1538] GAM117 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM117 was detected is described hereinabove with reference to Figs. 2-8.

[1539] GAM117 gene, herein designated GAM GENE, and GAM117 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1540] GAM117 gene, herein designated GAM GENE, encodes a GAM117 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM117 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM117 precursor RNA is designated SEQ ID:1616, and is provided hereinbelow with reference to the sequence listing part.

[1541] GAM117 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM117 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1542] An enzyme complex designated DICER COMPLEX, dices the GAM117 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM117 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 75%) nucleotide sequence of

GAM117 RNA is designated SEQ ID:1617, and is provided hereinbelow with reference to the sequence listing part.

[1543] GAM117 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM117 target RNA, herein designated GAM TARGET RNA. GAM117 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1544] GAM117 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM117 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM117 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM117 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM117 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1545] The complementary binding of GAM117 RNA, herein designated GAM RNA, to target binding sites on GAM117 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM117 target RNA, herein designated GAM TARGET RNA, into GAM117 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1546] It is appreciated that GAM117 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM117 target genes. The mRNA of each one of this plurality of GAM117 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM117 RNA, herein designated GAM RNA, and which when bound by GAM117 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM117 target proteins.

[1547] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM117 gene, herein designated GAM GENE, on one or more GAM117 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1548] It is yet further appreciated that specific functions, and accordingly utilities, of GAM117 correlate with, and may be deduced from, the identity of the target genes which GAM117 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1549] Nucleotide sequences of the GAM117 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM117 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM117 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM117 are further described hereinbelow with reference to Table Table1.

[1550] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM117 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1551]

[1552] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 118 (GAM118) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1553] GAM118 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM118 was detected is described hereinabove

with reference to Figs. 2-8.

[1554] GAM118 gene, herein designated GAM GENE, and GAM118 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1555] GAM118 gene, herein designated GAM GENE, encodes a GAM118 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM118 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM118 precursor RNA is designated SEQ ID:1655, and is provided hereinbelow with reference to the sequence listing part.

[1556] GAM118 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM118 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1557] An enzyme complex designated DICER COMPLEX, dices the GAM118 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM118 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 78%) nucleotide sequence of GAM118 RNA is designated SEQ ID:1617, and is provided hereinbelow with reference to the sequence listing part.

[1558] GAM118 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM118 target RNA, herein designated GAM TARGET RNA. GAM118 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1559] GAM118 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM118 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM118 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM118 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM118 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1560] The complementary binding of GAM118 RNA, herein designated GAM RNA, to target binding sites on GAM118 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM118 target RNA, herein designated GAM TARGET RNA, into GAM118 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[1561] It is appreciated that GAM118 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM118 target genes. The mRNA of each one of this plurality of GAM118 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM118 RNA, herein designated GAM RNA, and which when bound by GAM118 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM118 target proteins.

[1562] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM118 gene, herein designated GAM GENE, on one or more GAM118 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1563] It is yet further appreciated that specific functions, and accordingly utilities, of GAM118 correlate with, and may be deduced from, the identity of the target genes which GAM118 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1564] Nucleotide sequences of the GAM118 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM118 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM118 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM118 are further described hereinbelow with reference to Table Table1.

[1565] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM118 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1566]

[1567] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 119 (GAM119) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1568] GAM119 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM119 was detected is described hereinabove with reference to Figs. 2-8.

[1569] GAM119 gene, herein designated GAM GENE, and GAM119 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1570] GAM119 gene, herein designated GAM GENE, encodes a GAM119 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM119 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM119 precursor RNA is designated SEQ ID:1667, and is provided hereinbelow with reference to the sequence listing part.

[1571] GAM119 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM119 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1572] An enzyme complex designated DICER COMPLEX, dices the GAM119 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM119 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 17%) nucleotide sequence of GAM119 RNA is designated SEQ ID:1668, and is provided hereinbelow with reference to the sequence listing part.

[1573] GAM119 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM119 target RNA, herein designated GAM TARGET RNA.

GAM119 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1574] GAM119 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM119 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM119 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM119 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM119 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1575] The complementary binding of GAM119 RNA, herein designated GAM RNA, to target binding sites on GAM119 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM119 target RNA, herein designated GAM TARGET RNA, into GAM119 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1576] It is appreciated that GAM119 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM119 target genes. The mRNA of each one of this plurality of GAM119 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM119 RNA, herein designated GAM RNA, and which when bound by GAM119 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM119 target proteins.

[1577] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM119 gene, herein designated GAM GENE, on one or more GAM119 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1578] It is yet further appreciated that specific functions, and accordingly utilities, of GAM119 correlate with, and may be deduced from, the identity of the target genes which GAM119 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1579] Nucleotide sequences of the GAM119 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM119 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM119 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM119 are further described hereinbelow with reference to Table Table1.

[1580] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM119 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1581]

[1582] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 120 (GAM120) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1583] GAM120 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM120 was detected is described hereinabove with reference to Figs. 2-8.

[1584] GAM120 gene, herein designated GAM GENE, and GAM120 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1585] GAM120 gene, herein designated GAM GENE, encodes a

GAM120 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM120 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM120 precursor RNA is designated SEQ ID:1684, and is provided hereinbelow with reference to the sequence listing part.

[1586] GAM120 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM120 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1587] An enzyme complex designated DICER COMPLEX, dices the GAM120 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM120 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM120 RNA is designated SEQ ID:1685, and is provided hereinbelow with reference to the sequence listing part.

[1588] GAM120 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM120 target RNA, herein designated GAM TARGET RNA. GAM120 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1589] GAM120 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM120 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM120 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM120 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM120 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1590] The complementary binding of GAM120 RNA, herein designated GAM RNA, to target binding sites on GAM120 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM120 target RNA, herein designated GAM TARGET RNA, into GAM120 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1591] It is appreciated that GAM120 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM120 target genes. The mRNA of each one of this plurality of GAM120 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM120 RNA, herein designated GAM RNA, and which when bound by GAM120 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM120 target proteins.

[1592] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM120 gene, herein designated GAM GENE, on one or more GAM120 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1593] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM120 correlate with, and may be deduced from, the identity of the target genes which GAM120 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1594] Nucleotide sequences of the GAM120 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM120 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM120 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM120 are further described hereinbelow with reference to Table Table1.

[1595] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM120 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1596]

[1597] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 121 (GAM121) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[1598] GAM121 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM121 was detected is described hereinabove with reference to Figs. 2-8.

[1599] GAM121 gene, herein designated GAM GENE, and GAM121 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1600] GAM121 gene, herein designated GAM GENE, encodes a GAM121 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM121 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM121 precursor RNA is designated SEQ ID:1699, and is provided hereinbelow with reference to the sequence listing part.

[1601] GAM121 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM121 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1602] An enzyme complex designated DICER COMPLEX, dices the GAM121 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM121 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM121 RNA is designated SEQ ID:1700, and is provided hereinbelow with reference to the sequence listing part.

[1603] GAM121 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM121 target RNA, herein designated GAM TARGET RNA. GAM121 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1604] GAM121 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM121 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM121 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM121 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM121 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1605] The complementary binding of GAM121 RNA, herein designated GAM RNA, to target binding sites on GAM121 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM121 target RNA, herein designated GAM TARGET RNA, into GAM121 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1606] It is appreciated that GAM121 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM121 target genes. The mRNA of each one of this plurality of GAM121 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM121 RNA, herein designated GAM RNA, and which when bound by GAM121 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM121 target proteins.

[1607] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM121 gene, herein designated GAM GENE, on one or more GAM121 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1608] It is yet further appreciated that specific functions, and accordingly utilities, of GAM121 correlate with, and may be deduced from, the identity of the target genes which GAM121 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1609] Nucleotide sequences of the GAM121 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM121 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM121 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM121 are further described hereinbelow with reference to Table Table1.

[1610] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM121 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1611]

[1612] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 122 (GAM122) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1613] GAM122 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM122 was detected is described hereinabove with reference to Figs. 2-8.

[1614] GAM122 gene, herein designated GAM GENE, and GAM122 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1615] GAM122 gene, herein designated GAM GENE, encodes a GAM122 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM122 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM122 precursor RNA is designated SEQ ID:1702, and is provided hereinbelow with reference to the sequence listing part.

[1616] GAM122 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM122 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1617] An enzyme complex designated DICER COMPLEX, dices the GAM122 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM122 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM122 RNA is designated SEQ ID:1703, and is provided

hereinbelow with reference to the sequence listing part.

[1618] GAM122 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM122 target RNA, herein designated GAM TARGET RNA.
GAM122 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1619] GAM122 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM122 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM122 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM122 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM122 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1620] The complementary binding of GAM122 RNA, herein designated GAM RNA, to target binding sites on GAM122 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM122 target RNA, herein designated GAM TARGET RNA, into GAM122 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1621] It is appreciated that GAM122 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM122 target genes. The mRNA of each one of this plurality of GAM122 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM122 RNA, herein designated GAM RNA, and which when bound by GAM122 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM122 tar-

get proteins.

[1622] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM122 gene, herein designated GAM GENE, on one or more GAM122 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1623] It is yet further appreciated that specific functions, and accordingly utilities, of GAM122 correlate with, and may be deduced from, the identity of the target genes which GAM122 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1624] Nucleotide sequences of the GAM122 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM122 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM122 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM122 are further described hereinbelow with reference to Table Table1.

[1625] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM122 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1626]

[1627] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 123 (GAM123) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1628] GAM123 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM123 was detected is described hereinabove with reference to Figs. 2-8.

[1629] GAM123 gene, herein designated GAM GENE, and GAM123 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1630] GAM123 gene, herein designated GAM GENE, encodes a GAM123 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM123 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM123 precursor RNA is designated SEQ ID:1722, and is provided hereinbelow with reference to the sequence listing part.

[1631] GAM123 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM123 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1632] An enzyme complex designated DICER COMPLEX, dices

the GAM123 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM123 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM123 RNA is designated SEQ ID:1723, and is provided hereinbelow with reference to the sequence listing part.

[1633] GAM123 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM123 target RNA, herein designated GAM TARGET RNA.
GAM123 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1634] GAM123 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM123 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM123

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM123 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM123 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1635] The complementary binding of GAM123 RNA, herein designated GAM RNA, to target binding sites on GAM123 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM123 target RNA, herein designated GAM TARGET RNA, into GAM123 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1636] It is appreciated that GAM123 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM123 target genes. The mRNA of each one of this plurality of GAM123 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM123 RNA, herein designated GAM RNA, and which when bound by GAM123 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM123 target proteins.

[1637] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM123 gene, herein designated GAM GENE, on one or more GAM123 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1638] It is yet further appreciated that specific functions, and accordingly utilities, of GAM123 correlate with, and may be deduced from, the identity of the target genes which GAM123 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1639] Nucleotide sequences of the GAM123 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM123 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM123 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM123 are further described hereinbelow with reference to Table Table1.

[1640] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM123 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1641]

[1642] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 124 (GAM124) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1643] GAM124 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM124 was detected is described hereinabove with reference to Figs. 2-8.

[1644] GAM124 gene, herein designated GAM GENE, and GAM124 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1645] GAM124 gene, herein designated GAM GENE, encodes a GAM124 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM124 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM124 precursor RNA is designated SEQ ID:1734, and is provided hereinbelow with reference to the sequence listing part.

[1646] GAM124 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM124 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1647] An enzyme complex designated DICER COMPLEX, dices the GAM124 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM124 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM124 RNA is designated SEQ ID:1735, and is provided hereinbelow with reference to the sequence listing part.

[1648] GAM124 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM124 target RNA, herein designated GAM TARGET RNA. GAM124 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1649] GAM124 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM124 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM124 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM124 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM124 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[1650] The complementary binding of GAM124 RNA, herein designated GAM RNA, to target binding sites on GAM124 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM124 target RNA, herein designated GAM TARGET RNA, into GAM124 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1651] It is appreciated that GAM124 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM124 target genes. The mRNA of each one of this plurality of GAM124 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM124 RNA, herein designated GAM RNA, and which when bound by GAM124 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM124 target proteins.

[1652] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM124 gene, herein designated GAM GENE, on one or

more GAM124 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1653] It is yet further appreciated that specific functions, and accordingly utilities, of GAM124 correlate with, and may be deduced from, the identity of the target genes which GAM124 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1654] Nucleotide sequences of the GAM124 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM124 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM124 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM124 are further de-

scribed hereinbelow with reference to Table Table1.

[1655] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM124 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1656]

[1657] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 125 (GAM125) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1658] GAM125 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM125 was detected is described hereinabove with reference to Figs. 2-8.

[1659] GAM125 gene, herein designated GAM GENE, and GAM125 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1660] GAM125 gene, herein designated GAM GENE, encodes a GAM125 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM125 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM125 precursor RNA is designated SEQ ID:1741, and is provided hereinbelow with reference to the sequence listing part.

[1661] GAM125 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM125 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1662] An enzyme complex designated DICER COMPLEX, dices the GAM125 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM125 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 21%) nucleotide sequence of GAM125 RNA is designated SEQ ID:1742, and is provided hereinbelow with reference to the sequence listing part.

[1663] GAM125 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM125 target RNA, herein designated GAM TARGET RNA. GAM125 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1664] GAM125 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM125 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM125 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM125 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM125 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1665] The complementary binding of GAM125 RNA, herein designated GAM RNA, to target binding sites on GAM125 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM125 target RNA, herein designated GAM TARGET RNA, into GAM125 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1666] It is appreciated that GAM125 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM125 target genes. The mRNA of each one of this plurality of GAM125 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM125 RNA, herein designated GAM RNA, and which when bound by GAM125 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM125 target proteins.

[1667] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM125 gene, herein designated GAM GENE, on one or more GAM125 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1668] It is yet further appreciated that specific functions, and accordingly utilities, of GAM125 correlate with, and may

be deduced from, the identity of the target genes which GAM125 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1669] Nucleotide sequences of the GAM125 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM125 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM125 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM125 are further described hereinbelow with reference to Table Table1.

[1670] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM125 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1671]

[1672] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 126 (GAM126) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1673] GAM126 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM126 was detected is described hereinabove with reference to Figs. 2-8.

[1674] GAM126 gene, herein designated GAM GENE, and GAM126 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1675] GAM126 gene, herein designated GAM GENE, encodes a GAM126 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM126 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM126 precursor RNA is designated SEQ ID:1770, and is provided hereinbelow with reference to the sequence listing part.

[1676] GAM126 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM126 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1677] An enzyme complex designated DICER COMPLEX, dices the GAM126 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM126 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM126 RNA is designated SEQ ID:1771, and is provided hereinbelow with reference to the sequence listing part.

[1678] GAM126 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM126 target RNA, herein designated GAM TARGET RNA. GAM126 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1679] GAM126 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM126 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM126 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM126 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM126 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1680] The complementary binding of GAM126 RNA, herein designated GAM RNA, to target binding sites on GAM126 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM126 target RNA, herein designated GAM TARGET RNA, into GAM126 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1681] It is appreciated that GAM126 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM126 target genes. The mRNA of each one of this plurality of GAM126 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM126 RNA, herein designated GAM RNA, and which when bound by GAM126 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM126 target proteins.

[1682] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM126 gene, herein designated GAM GENE, on one or more GAM126 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1683] It is yet further appreciated that specific functions, and accordingly utilities, of GAM126 correlate with, and may be deduced from, the identity of the target genes which GAM126 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1684] Nucleotide sequences of the GAM126 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM126 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM126 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM126 are further described hereinbelow with reference to Table Table1.

[1685] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM126 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1686]

[1687] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 127 (GAM127) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1688] GAM127 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM127 was detected is described hereinabove with reference to Figs. 2-8.

[1689] GAM127 gene, herein designated GAM GENE, and GAM127 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1690] GAM127 gene, herein designated GAM GENE, encodes a GAM127 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM127 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM127 precursor RNA is desig-

nated SEQ ID:1780, and is provided hereinbelow with reference to the sequence listing part.

[1691] GAM127 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM127 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1692] An enzyme complex designated DICER COMPLEX, dices the GAM127 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM127 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 75%) nucleotide sequence of GAM127 RNA is designated SEQ ID:1781, and is provided hereinbelow with reference to the sequence listing part.

[1693] GAM127 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM127 target RNA, herein designated GAM TARGET RNA. GAM127 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1694] GAM127 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM127 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM127 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM127 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM127

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1695] The complementary binding of GAM127 RNA, herein designated GAM RNA, to target binding sites on GAM127 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM127 target RNA, herein designated GAM TARGET RNA, into GAM127 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1696] It is appreciated that GAM127 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM127 target genes. The mRNA of each one of this plurality of GAM127 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM127 RNA, herein designated GAM RNA, and which when bound by GAM127 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM127 target proteins.

[1697] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM127 gene, herein designated GAM GENE, on one or more GAM127 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1698] It is yet further appreciated that specific functions, and accordingly utilities, of GAM127 correlate with, and may be deduced from, the identity of the target genes which GAM127 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1699] Nucleotide sequences of the GAM127 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM127 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM127 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM127 are further described hereinbelow with reference to Table Table1.

[1700] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM127 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1701]

[1702] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 128 (GAM128) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1703] GAM128 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM128 was detected is described hereinabove with reference to Figs. 2-8.

[1704] GAM128 gene, herein designated GAM GENE, and

GAM128 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1705] GAM128 gene, herein designated GAM GENE, encodes a GAM128 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM128 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM128 precursor RNA is designated SEQ ID:1786, and is provided hereinbelow with reference to the sequence listing part.

[1706] GAM128 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM128 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1707] An enzyme complex designated DICER COMPLEX, dices the GAM128 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM128 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 19%) nucleotide sequence of GAM128 RNA is designated SEQ ID:1787, and is provided hereinbelow with reference to the sequence listing part.

[1708] GAM128 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM128 target RNA, herein designated GAM TARGET RNA. GAM128 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1709] GAM128 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM128 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM128 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM128 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM128 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1710] The complementary binding of GAM128 RNA, herein designated GAM RNA, to target binding sites on GAM128 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM128 target RNA, herein designated GAM TARGET RNA, into GAM128 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1711] It is appreciated that GAM128 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM128 target genes. The mRNA of each one of this plurality of GAM128 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM128 RNA, herein designated GAM RNA, and which when bound by GAM128 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM128 target proteins.

[1712] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM128 gene, herein designated GAM GENE, on one or more GAM128 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1713] It is yet further appreciated that specific functions, and accordingly utilities, of GAM128 correlate with, and may be deduced from, the identity of the target genes which GAM128 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1714] Nucleotide sequences of the GAM128 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM128 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM128 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM128 are further described hereinbelow with reference to Table Table1.

[1715] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM128 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1716]

[1717] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 129 (GAM129) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1718] GAM129 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM129 was detected is described hereinabove with reference to Figs. 2-8.

[1719] GAM129 gene, herein designated GAM GENE, and GAM129 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1720] GAM129 gene, herein designated GAM GENE, encodes a GAM129 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM129 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM129 precursor RNA is designated SEQ ID:1803, and is provided hereinbelow with reference to the sequence listing part.

[1721] GAM129 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM129 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1722] An enzyme complex designated DICER COMPLEX, dices the GAM129 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM129 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 28%) nucleotide sequence of GAM129 RNA is designated SEQ ID:1804, and is provided hereinbelow with reference to the sequence listing part.

[1723] GAM129 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM129 target RNA, herein designated GAM TARGET RNA. GAM129 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1724] GAM129 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM129 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM129 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM129 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM129 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1725] The complementary binding of GAM129 RNA, herein designated GAM RNA, to target binding sites on GAM129 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM129 target RNA, herein designated GAM TARGET RNA, into GAM129 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1726] It is appreciated that GAM129 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM129 target genes. The mRNA of each one of this plurality of GAM129 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM129 RNA, herein designated GAM RNA, and which when bound by GAM129 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM129 target proteins.

[1727] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM129 gene, herein designated GAM GENE, on one or more GAM129 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1728] It is yet further appreciated that specific functions, and accordingly utilities, of GAM129 correlate with, and may be deduced from, the identity of the target genes which GAM129 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1729] Nucleotide sequences of the GAM129 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM129 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM129 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM129 are further described hereinbelow with reference to Table Table1.

[1730] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM129 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1731]

[1732] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 130 (GAM130) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1733] GAM130 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM130 was detected is described hereinabove with reference to Figs. 2-8.

[1734] GAM130 gene, herein designated GAM GENE, and GAM130 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1735] GAM130 gene, herein designated GAM GENE, encodes a GAM130 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM130 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM130 precursor RNA is designated SEQ ID:1812, and is provided hereinbelow with reference to the sequence listing part.

[1736] GAM130 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM130 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1737] An enzyme complex designated DICER COMPLEX, dices the GAM130 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM130 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM130 RNA is designated SEQ ID:1813, and is provided hereinbelow with reference to the sequence listing part.

[1738] GAM130 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM130 target RNA, herein designated GAM TARGET RNA. GAM130 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1739] GAM130 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM130 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM130 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM130 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM130 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1740] The complementary binding of GAM130 RNA, herein designated GAM RNA, to target binding sites on GAM130 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM130 target RNA, herein designated GAM TARGET RNA, into GAM130 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1741] It is appreciated that GAM130 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM130 target genes. The mRNA of each one of this plurality of GAM130 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM130 RNA,

herein designated GAM RNA, and which when bound by GAM130 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM130 target proteins.

[1742] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM130 gene, herein designated GAM GENE, on one or more GAM130 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1743] It is yet further appreciated that specific functions, and accordingly utilities, of GAM130 correlate with, and may be deduced from, the identity of the target genes which

GAM130 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1744] Nucleotide sequences of the GAM130 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM130 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM130 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM130 are further described hereinbelow with reference to Table Table1.

[1745] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM130 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1746]

[1747] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 131 (GAM131) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1748] GAM131 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM131 was detected is described hereinabove with reference to Figs. 2-8.

[1749] GAM131 gene, herein designated GAM GENE, and GAM131 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1750] GAM131 gene, herein designated GAM GENE, encodes a GAM131 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM131 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM131 precursor RNA is designated SEQ ID:1825, and is provided hereinbelow with reference to the sequence listing part.

[1751] GAM131 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM131 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[1752] An enzyme complex designated DICER COMPLEX, dices the GAM131 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM131 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM131 RNA is designated SEQ ID:1826, and is provided hereinbelow with reference to the sequence listing part.

[1753] GAM131 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM131 target RNA, herein designated GAM TARGET RNA.
GAM131 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1754] GAM131 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM131 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM131 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM131 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM131 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1755] The complementary binding of GAM131 RNA, herein designated GAM RNA, to target binding sites on GAM131 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM131 target RNA, herein desig-

nated GAM TARGET RNA, into GAM131 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1756] It is appreciated that GAM131 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM131 target genes. The mRNA of each one of this plurality of GAM131 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM131 RNA, herein designated GAM RNA, and which when bound by GAM131 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM131 target proteins.

[1757] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM131 gene, herein designated GAM GENE, on one or more GAM131 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1758] It is yet further appreciated that specific functions, and accordingly utilities, of GAM131 correlate with, and may be deduced from, the identity of the target genes which GAM131 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1759] Nucleotide sequences of the GAM131 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM131 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM131 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM131 are further described hereinbelow with reference to Table Table1.

[1760] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM131 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[1761]

[1762] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 132 (GAM132) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1763] GAM132 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM132 was detected is described hereinabove with reference to Figs. 2-8.

[1764] GAM132 gene, herein designated GAM GENE, and GAM132 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1765] GAM132 gene, herein designated GAM GENE, encodes a GAM132 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM132 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM132 precursor RNA is designated SEQ ID:1842, and is provided hereinbelow with ref-

erence to the sequence listing part.

[1766] GAM132 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM132 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1767] An enzyme complex designated DICER COMPLEX, dices the GAM132 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM132 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 20%) nucleotide sequence of GAM132 RNA is designated SEQ ID:1843, and is provided hereinbelow with reference to the sequence listing part.

[1768] GAM132 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM132 target RNA, herein designated GAM TARGET RNA.

GAM132 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1769] GAM132 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM132 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM132 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM132 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM132 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1770] The complementary binding of GAM132 RNA, herein designated GAM RNA, to target binding sites on GAM132 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM132 target RNA, herein designated GAM TARGET RNA, into GAM132 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1771] It is appreciated that GAM132 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM132 target genes. The mRNA of each one of this plurality of GAM132 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM132 RNA, herein designated GAM RNA, and which when bound by GAM132 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM132 target proteins.

[1772] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM132 gene, herein designated GAM GENE, on one or more GAM132 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1773] It is yet further appreciated that specific functions, and accordingly utilities, of GAM132 correlate with, and may be deduced from, the identity of the target genes which GAM132 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1774] Nucleotide sequences of the GAM132 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM132 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM132 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM132 are further described hereinbelow with reference to Table Table1.

[1775] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM132 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1776]

[1777] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 133 (GAM133) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1778] GAM133 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM133 was detected is described hereinabove with reference to Figs. 2-8.

[1779] GAM133 gene, herein designated GAM GENE, and GAM133 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[1780] GAM133 gene, herein designated GAM GENE, encodes a GAM133 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM133 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM133 precursor RNA is designated SEQ ID:1857, and is provided hereinbelow with reference to the sequence listing part.

[1781] GAM133 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM133 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1782] An enzyme complex designated DICER COMPLEX, dices the GAM133 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM133 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM133 RNA is designated SEQ ID:1858, and is provided hereinbelow with reference to the sequence listing part.

[1783] GAM133 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM133 target RNA, herein designated GAM TARGET RNA. GAM133 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1784] GAM133 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM133 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM133 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM133 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM133 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1785] The complementary binding of GAM133 RNA, herein designated GAM RNA, to target binding sites on GAM133 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM133 target RNA, herein designated GAM TARGET RNA, into GAM133 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1786] It is appreciated that GAM133 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM133 target genes. The mRNA of each one of this plurality of GAM133 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM133 RNA, herein designated GAM RNA, and which when bound by GAM133 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM133 target proteins.

[1787] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM133 gene, herein designated GAM GENE, on one or more GAM133 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[1788] It is yet further appreciated that specific functions, and accordingly utilities, of GAM133 correlate with, and may be deduced from, the identity of the target genes which GAM133 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1789] Nucleotide sequences of the GAM133 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM133 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM133 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM133 are further described hereinbelow with reference to Table Table1.

[1790] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM133 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1791]

[1792] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

134 (GAM134) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1793] GAM134 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM134 was detected is described hereinabove with reference to Figs. 2-8.

[1794] GAM134 gene, herein designated GAM GENE, and GAM134 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1795] GAM134 gene, herein designated GAM GENE, encodes a GAM134 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM134 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM134 precursor RNA is designated SEQ ID:1880, and is provided hereinbelow with reference to the sequence listing part.

[1796] GAM134 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM134 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1797] An enzyme complex designated DICER COMPLEX, dices the GAM134 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM134 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM134 RNA is designated SEQ ID:1881, and is provided hereinbelow with reference to the sequence listing part.

[1798] GAM134 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM134 target RNA, herein designated GAM TARGET RNA. GAM134 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1799] GAM134 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM134 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM134 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM134 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM134 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1800] The complementary binding of GAM134 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM134 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM134 target RNA, herein designated GAM TARGET RNA, into GAM134 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1801] It is appreciated that GAM134 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM134 target genes. The mRNA of each one of this plurality of GAM134 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM134 RNA, herein designated GAM RNA, and which when bound by GAM134 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM134 target proteins.

[1802] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM134 gene, herein designated GAM GENE, on one or more GAM134 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1803] It is yet further appreciated that specific functions, and accordingly utilities, of GAM134 correlate with, and may be deduced from, the identity of the target genes which GAM134 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1804] Nucleotide sequences of the GAM134 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM134 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM134 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM134 are further described hereinbelow with reference to Table Table1.

[1805] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM134 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1806]

[1807] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 135 (GAM135) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1808] GAM135 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM135 was detected is described hereinabove with reference to Figs. 2-8.

[1809] GAM135 gene, herein designated GAM GENE, and GAM135 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1810] GAM135 gene, herein designated GAM GENE, encodes a GAM135 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM135 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM135 precursor RNA is designated SEQ ID:1887, and is provided hereinbelow with reference to the sequence listing part.

[1811] GAM135 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM135 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1812] An enzyme complex designated DICER COMPLEX, dices the GAM135 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM135 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 57%) nucleotide sequence of GAM135 RNA is designated SEQ ID:1888, and is provided hereinbelow with reference to the sequence listing part.

[1813] GAM135 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM135 target RNA, herein designated GAM TARGET RNA. GAM135 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1814] GAM135 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM135 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM135 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM135 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM135 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1815] The complementary binding of GAM135 RNA, herein designated GAM RNA, to target binding sites on GAM135 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM135 target RNA, herein designated GAM TARGET RNA, into GAM135 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1816] It is appreciated that GAM135 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM135 target genes. The mRNA of each one of this plurality of GAM135 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM135 RNA, herein designated GAM RNA, and which when bound by

GAM135 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM135 target proteins.

[1817] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM135 gene, herein designated GAM GENE, on one or more GAM135 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1818] It is yet further appreciated that specific functions, and accordingly utilities, of GAM135 correlate with, and may be deduced from, the identity of the target genes which GAM135 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[1819] Nucleotide sequences of the GAM135 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM135 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM135 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM135 are further described hereinbelow with reference to Table Table1.

[1820] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM135 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1821]

[1822] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 136 (GAM136) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1823] GAM136 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM136 was detected is described hereinabove with reference to Figs. 2-8.

[1824] GAM136 gene, herein designated GAM GENE, and GAM136 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1825] GAM136 gene, herein designated GAM GENE, encodes a GAM136 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM136 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM136 precursor RNA is designated SEQ ID:1898, and is provided hereinbelow with reference to the sequence listing part.

[1826] GAM136 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM136 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[1827] An enzyme complex designated DICER COMPLEX, dices the GAM136 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM136 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM136 RNA is designated SEQ ID:1899, and is provided hereinbelow with reference to the sequence listing part.

[1828] GAM136 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM136 target RNA, herein designated GAM TARGET RNA. GAM136 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1829] GAM136 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM136 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM136 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM136 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM136 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1830] The complementary binding of GAM136 RNA, herein designated GAM RNA, to target binding sites on GAM136 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM136 target RNA, herein designated GAM TARGET RNA, into GAM136 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1831] It is appreciated that GAM136 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM136 target genes. The mRNA of each one of this plurality of GAM136 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM136 RNA, herein designated GAM RNA, and which when bound by GAM136 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM136 target proteins.

[1832] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM136 gene, herein designated GAM GENE, on one or more GAM136 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1833] It is yet further appreciated that specific functions, and accordingly utilities, of GAM136 correlate with, and may be deduced from, the identity of the target genes which GAM136 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1834] Nucleotide sequences of the GAM136 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM136 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM136 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM136 are further described hereinbelow with reference to Table Table1.

[1835] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM136 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1836]

[1837] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 137 (GAM137) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1838] GAM137 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM137 was detected is described hereinabove with reference to Figs. 2-8.

[1839] GAM137 gene, herein designated GAM GENE, and GAM137 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1840] GAM137 gene, herein designated GAM GENE, encodes a GAM137 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM137 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM137 precursor RNA is designated SEQ ID:1907, and is provided hereinbelow with reference to the sequence listing part.

[1841] GAM137 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM137 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1842] An enzyme complex designated DICER COMPLEX, dices the GAM137 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM137 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 79%) nucleotide sequence of GAM137 RNA is designated SEQ ID:1908, and is provided hereinbelow with reference to the sequence listing part.

[1843] GAM137 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM137

target RNA, herein designated GAM TARGET RNA.

GAM137 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1844] GAM137 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM137 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM137 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM137 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM137 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1845] The complementary binding of GAM137 RNA, herein designated GAM RNA, to target binding sites on GAM137 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM137 target RNA, herein designated GAM TARGET RNA, into GAM137 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1846] It is appreciated that GAM137 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM137 target genes. The mRNA of each one of this plurality of GAM137 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM137 RNA, herein designated GAM RNA, and which when bound by GAM137 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM137 target proteins.

[1847] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM137 gene, herein designated GAM GENE, on one or more GAM137 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1848] It is yet further appreciated that specific functions, and accordingly utilities, of GAM137 correlate with, and may be deduced from, the identity of the target genes which GAM137 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1849] Nucleotide sequences of the GAM137 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM137 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM137 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM137 are further described hereinbelow with reference to Table Table1.

[1850] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM137 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1851]

[1852] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 138 (GAM138) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1853] GAM138 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM138 was detected is described hereinabove with reference to Figs. 2-8.

[1854] GAM138 gene, herein designated GAM GENE, and GAM138 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1855] GAM138 gene, herein designated GAM GENE, encodes a GAM138 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM138 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM138 precursor RNA is designated SEQ ID:1922, and is provided hereinbelow with reference to the sequence listing part.

[1856] GAM138 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM138 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1857] An enzyme complex designated DICER COMPLEX, dices the GAM138 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM138 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM138 RNA is designated SEQ ID:1923, and is provided hereinbelow with reference to the sequence listing part.

[1858] GAM138 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM138 target RNA, herein designated GAM TARGET RNA. GAM138 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1859] GAM138 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM138 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM138 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM138 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM138 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1860] The complementary binding of GAM138 RNA, herein designated GAM RNA, to target binding sites on GAM138 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM138 target RNA, herein designated GAM TARGET RNA, into GAM138 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1861] It is appreciated that GAM138 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM138 target genes. The mRNA of each one of this plu-

rality of GAM138 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM138 RNA, herein designated GAM RNA, and which when bound by GAM138 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM138 target proteins.

[1862] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM138 gene, herein designated GAM GENE, on one or more GAM138 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1863] It is yet further appreciated that specific functions, and accordingly utilities, of GAM138 correlate with, and may be deduced from, the identity of the target genes which GAM138 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1864] Nucleotide sequences of the GAM138 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM138 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM138 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM138 are further described hereinbelow with reference to Table Table1.

[1865] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM138 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1866]

[1867] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 139 (GAM139) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[1868] GAM139 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM139 was detected is described hereinabove with reference to Figs. 2-8.

[1869] GAM139 gene, herein designated GAM GENE, and GAM139 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1870] GAM139 gene, herein designated GAM GENE, encodes a GAM139 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM139 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM139 precursor RNA is designated SEQ ID:1947, and is provided hereinbelow with reference to the sequence listing part.

[1871] GAM139 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM139 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1872] An enzyme complex designated DICER COMPLEX, dices the GAM139 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM139 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 38%) nucleotide sequence of GAM139 RNA is designated SEQ ID:1948, and is provided hereinbelow with reference to the sequence listing part.

[1873] GAM139 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM139 target RNA, herein designated GAM TARGET RNA.
GAM139 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[1874] GAM139 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM139 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM139 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM139 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM139 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1875] The complementary binding of GAM139 RNA, herein designated GAM RNA, to target binding sites on GAM139 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM139 target RNA, herein designated GAM TARGET RNA, into GAM139 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1876] It is appreciated that GAM139 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM139 target genes. The mRNA of each one of this plurality of GAM139 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM139 RNA, herein designated GAM RNA, and which when bound by GAM139 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM139 target proteins.

[1877] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM139 gene, herein designated GAM GENE, on one or more GAM139 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1878] It is yet further appreciated that specific functions, and accordingly utilities, of GAM139 correlate with, and may be deduced from, the identity of the target genes which GAM139 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1879] Nucleotide sequences of the GAM139 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM139 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM139 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM139 are further described hereinbelow with reference to Table Table1.

[1880] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM139 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1881]

[1882] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 140 (GAM140) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1883] GAM140 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM140 was detected is described hereinabove with reference to Figs. 2-8.

[1884] GAM140 gene, herein designated GAM GENE, and GAM140 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1885] GAM140 gene, herein designated GAM GENE, encodes a GAM140 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM140 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM140 precursor RNA is designated SEQ ID:1954, and is provided hereinbelow with reference to the sequence listing part.

[1886] GAM140 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM140 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1887] An enzyme complex designated DICER COMPLEX, dices the GAM140 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM140 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of

GAM140 RNA is designated SEQ ID:1955, and is provided hereinbelow with reference to the sequence listing part.

[1888] GAM140 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM140 target RNA, herein designated GAM TARGET RNA. GAM140 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1889] GAM140 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM140 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM140 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM140 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM140 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1890] The complementary binding of GAM140 RNA, herein designated GAM RNA, to target binding sites on GAM140 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM140 target RNA, herein designated GAM TARGET RNA, into GAM140 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1891] It is appreciated that GAM140 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM140 target genes. The mRNA of each one of this plurality of GAM140 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM140 RNA, herein designated GAM RNA, and which when bound by GAM140 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM140 target proteins.

[1892] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM140 gene, herein designated GAM GENE, on one or more GAM140 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1893] It is yet further appreciated that specific functions, and accordingly utilities, of GAM140 correlate with, and may be deduced from, the identity of the target genes which GAM140 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1894] Nucleotide sequences of the GAM140 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM140 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM140 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM140 are further described hereinbelow with reference to Table Table1.

[1895] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM140 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1896]

[1897] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 141 (GAM141) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1898] GAM141 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM141 was detected is described hereinabove

with reference to Figs. 2-8.

[1899] GAM141 gene, herein designated GAM GENE, and GAM141 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1900] GAM141 gene, herein designated GAM GENE, encodes a GAM141 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM141 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM141 precursor RNA is designated SEQ ID:1967, and is provided hereinbelow with reference to the sequence listing part.

[1901] GAM141 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM141 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1902] An enzyme complex designated DICER COMPLEX, dices the GAM141 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM141 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM141 RNA is designated SEQ ID:1968, and is provided hereinbelow with reference to the sequence listing part.

[1903] GAM141 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM141 target RNA, herein designated GAM TARGET RNA. GAM141 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1904] GAM141 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM141 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM141 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM141 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM141 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1905] The complementary binding of GAM141 RNA, herein designated GAM RNA, to target binding sites on GAM141 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM141 target RNA, herein designated GAM TARGET RNA, into GAM141 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[1906] It is appreciated that GAM141 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM141 target genes. The mRNA of each one of this plurality of GAM141 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM141 RNA, herein designated GAM RNA, and which when bound by GAM141 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM141 target proteins.

[1907] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM141 gene, herein designated GAM GENE, on one or more GAM141 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1908] It is yet further appreciated that specific functions, and accordingly utilities, of GAM141 correlate with, and may be deduced from, the identity of the target genes which GAM141 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1909] Nucleotide sequences of the GAM141 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM141 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM141 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM141 are further described hereinbelow with reference to Table Table1.

[1910] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM141 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1911]

[1912] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 142 (GAM142) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1913] GAM142 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM142 was detected is described hereinabove with reference to Figs. 2-8.

[1914] GAM142 gene, herein designated GAM GENE, and GAM142 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1915] GAM142 gene, herein designated GAM GENE, encodes a GAM142 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM142 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM142 precursor RNA is designated SEQ ID:1983, and is provided hereinbelow with reference to the sequence listing part.

[1916] GAM142 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM142 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1917] An enzyme complex designated DICER COMPLEX, dices the GAM142 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM142 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM142 RNA is designated SEQ ID:1984, and is provided hereinbelow with reference to the sequence listing part.

[1918] GAM142 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM142 target RNA, herein designated GAM TARGET RNA.

GAM142 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1919] GAM142 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM142 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM142 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM142 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM142 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1920] The complementary binding of GAM142 RNA, herein designated GAM RNA, to target binding sites on GAM142 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM142 target RNA, herein designated GAM TARGET RNA, into GAM142 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1921] It is appreciated that GAM142 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM142 target genes. The mRNA of each one of this plurality of GAM142 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM142 RNA, herein designated GAM RNA, and which when bound by GAM142 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM142 target proteins.

[1922] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM142 gene, herein designated GAM GENE, on one or more GAM142 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1923] It is yet further appreciated that specific functions, and accordingly utilities, of GAM142 correlate with, and may be deduced from, the identity of the target genes which GAM142 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1924] Nucleotide sequences of the GAM142 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM142 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM142 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM142 are further described hereinbelow with reference to Table Table1.

[1925] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM142 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1926]

[1927] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 143 (GAM143) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1928] GAM143 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM143 was detected is described hereinabove with reference to Figs. 2-8.

[1929] GAM143 gene, herein designated GAM GENE, and GAM143 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1930] GAM143 gene, herein designated GAM GENE, encodes a

GAM143 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM143 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM143 precursor RNA is designated SEQ ID:1992, and is provided hereinbelow with reference to the sequence listing part.

[1931] GAM143 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM143 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1932] An enzyme complex designated DICER COMPLEX, dices the GAM143 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM143 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 24%) nucleotide sequence of GAM143 RNA is designated SEQ ID:1993, and is provided hereinbelow with reference to the sequence listing part.

[1933] GAM143 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM143 target RNA, herein designated GAM TARGET RNA. GAM143 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1934] GAM143 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM143 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM143 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM143 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM143 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1935] The complementary binding of GAM143 RNA, herein designated GAM RNA, to target binding sites on GAM143 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM143 target RNA, herein designated GAM TARGET RNA, into GAM143 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1936] It is appreciated that GAM143 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM143 target genes. The mRNA of each one of this plurality of GAM143 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM143 RNA, herein designated GAM RNA, and which when bound by GAM143 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM143 target proteins.

[1937] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM143 gene, herein designated GAM GENE, on one or more GAM143 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1938] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM143 correlate with, and may be deduced from, the identity of the target genes which GAM143 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1939] Nucleotide sequences of the GAM143 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM143 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM143 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM143 are further described hereinbelow with reference to Table Table1.

[1940] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM143 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1941]

[1942] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 144 (GAM144) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[1943] GAM144 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM144 was detected is described hereinabove with reference to Figs. 2-8.

[1944] GAM144 gene, herein designated GAM GENE, and GAM144 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1945] GAM144 gene, herein designated GAM GENE, encodes a GAM144 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM144 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM144 precursor RNA is designated SEQ ID:2008, and is provided hereinbelow with reference to the sequence listing part.

[1946] GAM144 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM144 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1947] An enzyme complex designated DICER COMPLEX, dices the GAM144 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM144 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM144 RNA is designated SEQ ID:2009, and is provided hereinbelow with reference to the sequence listing part.

[1948] GAM144 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM144 target RNA, herein designated GAM TARGET RNA. GAM144 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1949] GAM144 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM144 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM144 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM144 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM144 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1950] The complementary binding of GAM144 RNA, herein designated GAM RNA, to target binding sites on GAM144 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM144 target RNA, herein designated GAM TARGET RNA, into GAM144 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1951] It is appreciated that GAM144 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM144 target genes. The mRNA of each one of this plurality of GAM144 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM144 RNA, herein designated GAM RNA, and which when bound by GAM144 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM144 target proteins.

[1952] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM144 gene, herein designated GAM GENE, on one or more GAM144 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1953] It is yet further appreciated that specific functions, and accordingly utilities, of GAM144 correlate with, and may be deduced from, the identity of the target genes which GAM144 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1954] Nucleotide sequences of the GAM144 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM144 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM144 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM144 are further described hereinbelow with reference to Table Table1.

[1955] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM144 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1956]

[1957] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 145 (GAM145) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1958] GAM145 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM145 was detected is described hereinabove with reference to Figs. 2-8.

[1959] GAM145 gene, herein designated GAM GENE, and GAM145 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1960] GAM145 gene, herein designated GAM GENE, encodes a GAM145 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM145 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM145 precursor RNA is designated SEQ ID:2020, and is provided hereinbelow with reference to the sequence listing part.

[1961] GAM145 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM145 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1962] An enzyme complex designated DICER COMPLEX, dices the GAM145 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM145 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM145 RNA is designated SEQ ID:2021, and is provided

hereinbelow with reference to the sequence listing part.

[1963] GAM145 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM145 target RNA, herein designated GAM TARGET RNA.

GAM145 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1964] GAM145 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM145 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM145 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM145 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM145 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1965] The complementary binding of GAM145 RNA, herein designated GAM RNA, to target binding sites on GAM145 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM145 target RNA, herein designated GAM TARGET RNA, into GAM145 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1966] It is appreciated that GAM145 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM145 target genes. The mRNA of each one of this plurality of GAM145 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM145 RNA, herein designated GAM RNA, and which when bound by GAM145 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM145 tar-

get proteins.

[1967] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM145 gene, herein designated GAM GENE, on one or more GAM145 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1968] It is yet further appreciated that specific functions, and accordingly utilities, of GAM145 correlate with, and may be deduced from, the identity of the target genes which GAM145 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1969] Nucleotide sequences of the GAM145 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM145 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM145 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM145 are further described hereinbelow with reference to Table Table1.

[1970] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM145 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1971]

[1972] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 146 (GAM146) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1973] GAM146 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM146 was detected is described hereinabove with reference to Figs. 2-8.

[1974] GAM146 gene, herein designated GAM GENE, and GAM146 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1975] GAM146 gene, herein designated GAM GENE, encodes a GAM146 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM146 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM146 precursor RNA is designated SEQ ID:2040, and is provided hereinbelow with reference to the sequence listing part.

[1976] GAM146 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM146 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1977] An enzyme complex designated DICER COMPLEX, dices

the GAM146 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM146 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 48%) nucleotide sequence of GAM146 RNA is designated SEQ ID:2041, and is provided hereinbelow with reference to the sequence listing part.

[1978] GAM146 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM146 target RNA, herein designated GAM TARGET RNA. GAM146 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1979] GAM146 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM146 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM146

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM146 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM146 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[1980] The complementary binding of GAM146 RNA, herein designated GAM RNA, to target binding sites on GAM146 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM146 target RNA, herein designated GAM TARGET RNA, into GAM146 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1981] It is appreciated that GAM146 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM146 target genes. The mRNA of each one of this plurality of GAM146 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM146 RNA, herein designated GAM RNA, and which when bound by GAM146 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM146 target proteins.

[1982] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM146 gene, herein designated GAM GENE, on one or more GAM146 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1983] It is yet further appreciated that specific functions, and accordingly utilities, of GAM146 correlate with, and may be deduced from, the identity of the target genes which GAM146 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1984] Nucleotide sequences of the GAM146 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM146 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM146 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM146 are further described hereinbelow with reference to Table Table1.

[1985] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM146 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[1986]

[1987] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 147 (GAM147) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[1988] GAM147 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM147 was detected is described hereinabove with reference to Figs. 2-8.

[1989] GAM147 gene, herein designated GAM GENE, and GAM147 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[1990] GAM147 gene, herein designated GAM GENE, encodes a GAM147 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM147 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM147 precursor RNA is designated SEQ ID:2112, and is provided hereinbelow with reference to the sequence listing part.

[1991] GAM147 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM147 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[1992] An enzyme complex designated DICER COMPLEX, dices the GAM147 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM147 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 22%) nucleotide sequence of GAM147 RNA is designated SEQ ID:2113, and is provided hereinbelow with reference to the sequence listing part.

[1993] GAM147 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM147 target RNA, herein designated GAM TARGET RNA. GAM147 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[1994] GAM147 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM147 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM147 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM147 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM147 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[1995] The complementary binding of GAM147 RNA, herein designated GAM RNA, to target binding sites on GAM147 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM147 target RNA, herein designated GAM TARGET RNA, into GAM147 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[1996] It is appreciated that GAM147 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM147 target genes. The mRNA of each one of this plurality of GAM147 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM147 RNA, herein designated GAM RNA, and which when bound by GAM147 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM147 target proteins.

[1997] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM147 gene, herein designated GAM GENE, on one or

more GAM147 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[1998] It is yet further appreciated that specific functions, and accordingly utilities, of GAM147 correlate with, and may be deduced from, the identity of the target genes which GAM147 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[1999] Nucleotide sequences of the GAM147 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM147 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM147 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM147 are further de-

scribed hereinbelow with reference to Table Table1.

[2000] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM147 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2001]

[2002] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 148 (GAM148) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2003] GAM148 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM148 was detected is described hereinabove with reference to Figs. 2-8.

[2004] GAM148 gene, herein designated GAM GENE, and GAM148 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2005] GAM148 gene, herein designated GAM GENE, encodes a GAM148 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM148 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM148 precursor RNA is designated SEQ ID:2125, and is provided hereinbelow with reference to the sequence listing part.

[2006] GAM148 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM148 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2007] An enzyme complex designated DICER COMPLEX, dices the GAM148 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM148 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM148 RNA is designated SEQ ID:2126, and is provided hereinbelow with reference to the sequence listing part.

[2008] GAM148 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM148 target RNA, herein designated GAM TARGET RNA. GAM148 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2009] GAM148 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM148 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM148 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM148 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM148 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2010] The complementary binding of GAM148 RNA, herein designated GAM RNA, to target binding sites on GAM148 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM148 target RNA, herein designated GAM TARGET RNA, into GAM148 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2011] It is appreciated that GAM148 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM148 target genes. The mRNA of each one of this plurality of GAM148 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM148 RNA, herein designated GAM RNA, and which when bound by GAM148 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM148 target proteins.

[2012] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM148 gene, herein designated GAM GENE, on one or more GAM148 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2013] It is yet further appreciated that specific functions, and accordingly utilities, of GAM148 correlate with, and may

be deduced from, the identity of the target genes which GAM148 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2014] Nucleotide sequences of the GAM148 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM148 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM148 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM148 are further described hereinbelow with reference to Table Table1.

[2015] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM148 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2016]

[2017] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 149 (GAM149) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2018] GAM149 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM149 was detected is described hereinabove with reference to Figs. 2-8.

[2019] GAM149 gene, herein designated GAM GENE, and GAM149 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2020] GAM149 gene, herein designated GAM GENE, encodes a GAM149 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM149 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM149 precursor RNA is designated SEQ ID:2132, and is provided hereinbelow with reference to the sequence listing part.

[2021] GAM149 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM149 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2022] An enzyme complex designated DICER COMPLEX, dices the GAM149 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM149 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM149 RNA is designated SEQ ID:2133, and is provided hereinbelow with reference to the sequence listing part.

[2023] GAM149 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM149 target RNA, herein designated GAM TARGET RNA. GAM149 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2024] GAM149 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM149 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM149 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM149 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM149 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2025] The complementary binding of GAM149 RNA, herein designated GAM RNA, to target binding sites on GAM149 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM149 target RNA, herein designated GAM TARGET RNA, into GAM149 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2026] It is appreciated that GAM149 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM149 target genes. The mRNA of each one of this plurality of GAM149 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM149 RNA, herein designated GAM RNA, and which when bound by GAM149 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM149 target proteins.

[2027] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM149 gene, herein designated GAM GENE, on one or more GAM149 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2028] It is yet further appreciated that specific functions, and accordingly utilities, of GAM149 correlate with, and may be deduced from, the identity of the target genes which GAM149 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2029] Nucleotide sequences of the GAM149 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM149 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM149 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM149 are further described hereinbelow with reference to Table Table1.

[2030] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM149 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2031]

[2032] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 150 (GAM150) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2033] GAM150 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM150 was detected is described hereinabove with reference to Figs. 2-8.

[2034] GAM150 gene, herein designated GAM GENE, and GAM150 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2035] GAM150 gene, herein designated GAM GENE, encodes a GAM150 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM150 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM150 precursor RNA is desig-

nated SEQ ID:2141, and is provided hereinbelow with reference to the sequence listing part.

[2036] GAM150 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM150 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2037] An enzyme complex designated DICER COMPLEX, dices the GAM150 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM150 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM150 RNA is designated SEQ ID:2142, and is provided hereinbelow with reference to the sequence listing part.

[2038] GAM150 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM150 target RNA, herein designated GAM TARGET RNA. GAM150 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2039] GAM150 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM150 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM150 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM150 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM150

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2040] The complementary binding of GAM150 RNA, herein designated GAM RNA, to target binding sites on GAM150 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM150 target RNA, herein designated GAM TARGET RNA, into GAM150 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2041] It is appreciated that GAM150 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM150 target genes. The mRNA of each one of this plurality of GAM150 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM150 RNA, herein designated GAM RNA, and which when bound by GAM150 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM150 target proteins.

[2042] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM150 gene, herein designated GAM GENE, on one or more GAM150 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2043] It is yet further appreciated that specific functions, and accordingly utilities, of GAM150 correlate with, and may be deduced from, the identity of the target genes which GAM150 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2044] Nucleotide sequences of the GAM150 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM150 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM150 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM150 are further described hereinbelow with reference to Table Table1.

[2045] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM150 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2046]

[2047] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 151 (GAM151) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2048] GAM151 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM151 was detected is described hereinabove with reference to Figs. 2-8.

[2049] GAM151 gene, herein designated GAM GENE, and

GAM151 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2050] GAM151 gene, herein designated GAM GENE, encodes a GAM151 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM151 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM151 precursor RNA is designated SEQ ID:2157, and is provided hereinbelow with reference to the sequence listing part.

[2051] GAM151 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM151 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2052] An enzyme complex designated DICER COMPLEX, dices the GAM151 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM151 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM151 RNA is designated SEQ ID:2158, and is provided hereinbelow with reference to the sequence listing part.

[2053] GAM151 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM151 target RNA, herein designated GAM TARGET RNA. GAM151 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2054] GAM151 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM151 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM151 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM151 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM151 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2055] The complementary binding of GAM151 RNA, herein designated GAM RNA, to target binding sites on GAM151 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM151 target RNA, herein designated GAM TARGET RNA, into GAM151 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2056] It is appreciated that GAM151 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM151 target genes. The mRNA of each one of this plurality of GAM151 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM151 RNA, herein designated GAM RNA, and which when bound by GAM151 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM151 target proteins.

[2057] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM151 gene, herein designated GAM GENE, on one or more GAM151 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2058] It is yet further appreciated that specific functions, and accordingly utilities, of GAM151 correlate with, and may be deduced from, the identity of the target genes which GAM151 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2059] Nucleotide sequences of the GAM151 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM151 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM151 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM151 are further described hereinbelow with reference to Table Table1.

[2060] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM151 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2061]

[2062] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 152 (GAM152) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2063] GAM152 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM152 was detected is described hereinabove with reference to Figs. 2-8.

[2064] GAM152 gene, herein designated GAM GENE, and GAM152 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2065] GAM152 gene, herein designated GAM GENE, encodes a GAM152 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM152 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM152 precursor RNA is designated SEQ ID:2170, and is provided hereinbelow with reference to the sequence listing part.

[2066] GAM152 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM152 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2067] An enzyme complex designated DICER COMPLEX, dices the GAM152 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM152 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM152 RNA is designated SEQ ID:2171, and is provided

hereinbelow with reference to the sequence listing part.

[2068] GAM152 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM152 target RNA, herein designated GAM TARGET RNA.
GAM152 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2069] GAM152 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM152 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM152 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM152 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM152 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2070] The complementary binding of GAM152 RNA, herein designated GAM RNA, to target binding sites on GAM152 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM152 target RNA, herein designated GAM TARGET RNA, into GAM152 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2071] It is appreciated that GAM152 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM152 target genes. The mRNA of each one of this plurality of GAM152 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM152 RNA, herein designated GAM RNA, and which when bound by GAM152 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM152 tar-

get proteins.

[2072] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM152 gene, herein designated GAM GENE, on one or more GAM152 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2073] It is yet further appreciated that specific functions, and accordingly utilities, of GAM152 correlate with, and may be deduced from, the identity of the target genes which GAM152 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2074] Nucleotide sequences of the GAM152 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM152 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM152 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM152 are further described hereinbelow with reference to Table Table1.

[2075] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM152 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2076]

[2077] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 153 (GAM153) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2078] GAM153 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM153 was detected is described hereinabove with reference to Figs. 2-8.

[2079] GAM153 gene, herein designated GAM GENE, and GAM153 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2080] GAM153 gene, herein designated GAM GENE, encodes a GAM153 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM153 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM153 precursor RNA is designated SEQ ID:2182, and is provided hereinbelow with reference to the sequence listing part.

[2081] GAM153 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM153 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2082] An enzyme complex designated DICER COMPLEX, dices

the GAM153 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM153 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM153 RNA is designated SEQ ID:2183, and is provided hereinbelow with reference to the sequence listing part.

[2083] GAM153 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM153 target RNA, herein designated GAM TARGET RNA. GAM153 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2084] GAM153 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM153 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM153

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM153 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM153 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2085] The complementary binding of GAM153 RNA, herein designated GAM RNA, to target binding sites on GAM153 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM153 target RNA, herein designated GAM TARGET RNA, into GAM153 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2086] It is appreciated that GAM153 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM153 target genes. The mRNA of each one of this plurality of GAM153 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM153 RNA, herein designated GAM RNA, and which when bound by GAM153 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM153 target proteins.

[2087] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM153 gene, herein designated GAM GENE, on one or more GAM153 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2088] It is yet further appreciated that specific functions, and accordingly utilities, of GAM153 correlate with, and may be deduced from, the identity of the target genes which GAM153 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2089] Nucleotide sequences of the GAM153 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM153 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM153 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM153 are further described hereinbelow with reference to Table Table1.

[2090] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM153 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2091]

[2092] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 154 (GAM154) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2093] GAM154 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM154 was detected is described hereinabove with reference to Figs. 2-8.

[2094] GAM154 gene, herein designated GAM GENE, and GAM154 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2095] GAM154 gene, herein designated GAM GENE, encodes a GAM154 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM154 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM154 precursor RNA is designated SEQ ID:2194, and is provided hereinbelow with reference to the sequence listing part.

[2096] GAM154 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM154 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2097] An enzyme complex designated DICER COMPLEX, dices the GAM154 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM154 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM154 RNA is designated SEQ ID:2195, and is provided hereinbelow with reference to the sequence listing part.

[2098] GAM154 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM154 target RNA, herein designated GAM TARGET RNA. GAM154 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2099] GAM154 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM154 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM154 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM154 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM154 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[2100] The complementary binding of GAM154 RNA, herein designated GAM RNA, to target binding sites on GAM154 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM154 target RNA, herein designated GAM TARGET RNA, into GAM154 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2101] It is appreciated that GAM154 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM154 target genes. The mRNA of each one of this plurality of GAM154 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM154 RNA, herein designated GAM RNA, and which when bound by GAM154 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM154 target proteins.

[2102] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM154 gene, herein designated GAM GENE, on one or

more GAM154 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2103] It is yet further appreciated that specific functions, and accordingly utilities, of GAM154 correlate with, and may be deduced from, the identity of the target genes which GAM154 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2104] Nucleotide sequences of the GAM154 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM154 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM154 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM154 are further de-

scribed hereinbelow with reference to Table Table1.

[2105] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM154 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2106]

[2107] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 155 (GAM155) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2108] GAM155 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM155 was detected is described hereinabove with reference to Figs. 2-8.

[2109] GAM155 gene, herein designated GAM GENE, and GAM155 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2110] GAM155 gene, herein designated GAM GENE, encodes a GAM155 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM155 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM155 precursor RNA is designated SEQ ID:2204, and is provided hereinbelow with reference to the sequence listing part.

[2111] GAM155 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM155 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2112] An enzyme complex designated DICER COMPLEX, dices the GAM155 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM155 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM155 RNA is designated SEQ ID:2205, and is provided hereinbelow with reference to the sequence listing part.

[2113] GAM155 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM155 target RNA, herein designated GAM TARGET RNA. GAM155 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2114] GAM155 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM155 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM155 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM155 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM155 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2115] The complementary binding of GAM155 RNA, herein designated GAM RNA, to target binding sites on GAM155 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM155 target RNA, herein designated GAM TARGET RNA, into GAM155 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2116] It is appreciated that GAM155 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM155 target genes. The mRNA of each one of this plurality of GAM155 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM155 RNA, herein designated GAM RNA, and which when bound by GAM155 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM155 target proteins.

[2117] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM155 gene, herein designated GAM GENE, on one or more GAM155 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2118] It is yet further appreciated that specific functions, and accordingly utilities, of GAM155 correlate with, and may

be deduced from, the identity of the target genes which GAM155 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2119] Nucleotide sequences of the GAM155 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM155 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM155 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM155 are further described hereinbelow with reference to Table Table1.

[2120] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM155 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2121]

[2122] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 156 (GAM156) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2123] GAM156 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM156 was detected is described hereinabove with reference to Figs. 2-8.

[2124] GAM156 gene, herein designated GAM GENE, and GAM156 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2125] GAM156 gene, herein designated GAM GENE, encodes a GAM156 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM156 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM156 precursor RNA is designated SEQ ID:2227, and is provided hereinbelow with reference to the sequence listing part.

[2126] GAM156 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM156 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2127] An enzyme complex designated DICER COMPLEX, dices the GAM156 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM156 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 49%) nucleotide sequence of GAM156 RNA is designated SEQ ID:2228, and is provided hereinbelow with reference to the sequence listing part.

[2128] GAM156 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM156 target RNA, herein designated GAM TARGET RNA. GAM156 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2129] GAM156 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM156 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM156 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM156 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM156 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2130] The complementary binding of GAM156 RNA, herein designated GAM RNA, to target binding sites on GAM156 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM156 target RNA, herein designated GAM TARGET RNA, into GAM156 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2131] It is appreciated that GAM156 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM156 target genes. The mRNA of each one of this plurality of GAM156 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM156 RNA, herein designated GAM RNA, and which when bound by GAM156 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM156 target proteins.

[2132] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM156 gene, herein designated GAM GENE, on one or more GAM156 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2133] It is yet further appreciated that specific functions, and accordingly utilities, of GAM156 correlate with, and may be deduced from, the identity of the target genes which GAM156 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2134] Nucleotide sequences of the GAM156 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM156 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM156 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM156 are further described hereinbelow with reference to Table Table1.

[2135] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM156 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2136]

[2137] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 157 (GAM157) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2138] GAM157 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM157 was detected is described hereinabove with reference to Figs. 2-8.

[2139] GAM157 gene, herein designated GAM GENE, and GAM157 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2140] GAM157 gene, herein designated GAM GENE, encodes a GAM157 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM157 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM157 precursor RNA is desig-

nated SEQ ID:2240, and is provided hereinbelow with reference to the sequence listing part.

[2141] GAM157 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM157 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2142] An enzyme complex designated DICER COMPLEX, dices the GAM157 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM157 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM157 RNA is designated SEQ ID:2241, and is provided hereinbelow with reference to the sequence listing part.

[2143] GAM157 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM157 target RNA, herein designated GAM TARGET RNA. GAM157 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2144] GAM157 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM157 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM157 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM157 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM157

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2145] The complementary binding of GAM157 RNA, herein designated GAM RNA, to target binding sites on GAM157 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM157 target RNA, herein designated GAM TARGET RNA, into GAM157 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2146] It is appreciated that GAM157 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM157 target genes. The mRNA of each one of this plurality of GAM157 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM157 RNA, herein designated GAM RNA, and which when bound by GAM157 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM157 target proteins.

[2147] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM157 gene, herein designated GAM GENE, on one or more GAM157 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2148] It is yet further appreciated that specific functions, and accordingly utilities, of GAM157 correlate with, and may be deduced from, the identity of the target genes which GAM157 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2149] Nucleotide sequences of the GAM157 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM157 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM157 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM157 are further described hereinbelow with reference to Table Table1.

[2150] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM157 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2151]

[2152] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 158 (GAM158) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2153] GAM158 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM158 was detected is described hereinabove with reference to Figs. 2-8.

[2154] GAM158 gene, herein designated GAM GENE, and

GAM158 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2155] GAM158 gene, herein designated GAM GENE, encodes a GAM158 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM158 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM158 precursor RNA is designated SEQ ID:2266, and is provided hereinbelow with reference to the sequence listing part.

[2156] GAM158 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM158 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2157] An enzyme complex designated DICER COMPLEX, dices the GAM158 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM158 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM158 RNA is designated SEQ ID:2267, and is provided hereinbelow with reference to the sequence listing part.

[2158] GAM158 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM158 target RNA, herein designated GAM TARGET RNA. GAM158 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2159] GAM158 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM158 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM158 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM158 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM158 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2160] The complementary binding of GAM158 RNA, herein designated GAM RNA, to target binding sites on GAM158 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM158 target RNA, herein designated GAM TARGET RNA, into GAM158 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2161] It is appreciated that GAM158 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM158 target genes. The mRNA of each one of this plurality of GAM158 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM158 RNA, herein designated GAM RNA, and which when bound by GAM158 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM158 target proteins.

[2162] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM158 gene, herein designated GAM GENE, on one or more GAM158 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2163] It is yet further appreciated that specific functions, and accordingly utilities, of GAM158 correlate with, and may be deduced from, the identity of the target genes which GAM158 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2164] Nucleotide sequences of the GAM158 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM158 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM158 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM158 are further described hereinbelow with reference to Table Table1.

[2165] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM158 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2166]

[2167] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 159 (GAM159) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2168] GAM159 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM159 was detected is described hereinabove with reference to Figs. 2-8.

[2169] GAM159 gene, herein designated GAM GENE, and GAM159 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2170] GAM159 gene, herein designated GAM GENE, encodes a GAM159 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM159 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM159 precursor RNA is designated SEQ ID:2277, and is provided hereinbelow with reference to the sequence listing part.

[2171] GAM159 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM159 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2172] An enzyme complex designated DICER COMPLEX, dices the GAM159 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM159 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM159 RNA is designated SEQ ID:2278, and is provided hereinbelow with reference to the sequence listing part.

[2173] GAM159 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM159 target RNA, herein designated GAM TARGET RNA. GAM159 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2174] GAM159 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM159 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM159 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM159 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM159 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2175] The complementary binding of GAM159 RNA, herein designated GAM RNA, to target binding sites on GAM159 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM159 target RNA, herein designated GAM TARGET RNA, into GAM159 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2176] It is appreciated that GAM159 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM159 target genes. The mRNA of each one of this plurality of GAM159 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM159 RNA, herein designated GAM RNA, and which when bound by GAM159 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM159 target proteins.

[2177] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM159 gene, herein designated GAM GENE, on one or more GAM159 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2178] It is yet further appreciated that specific functions, and accordingly utilities, of GAM159 correlate with, and may be deduced from, the identity of the target genes which GAM159 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2179] Nucleotide sequences of the GAM159 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM159 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM159 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM159 are further described hereinbelow with reference to Table Table1.

[2180] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM159 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2181]

[2182] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 160 (GAM160) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2183] GAM160 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM160 was detected is described hereinabove with reference to Figs. 2-8.

[2184] GAM160 gene, herein designated GAM GENE, and GAM160 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2185] GAM160 gene, herein designated GAM GENE, encodes a GAM160 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM160 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM160 precursor RNA is designated SEQ ID:2290, and is provided hereinbelow with reference to the sequence listing part.

[2186] GAM160 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM160 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2187] An enzyme complex designated DICER COMPLEX, dices the GAM160 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM160 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM160 RNA is designated SEQ ID:2291, and is provided hereinbelow with reference to the sequence listing part.

[2188] GAM160 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM160 target RNA, herein designated GAM TARGET RNA. GAM160 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2189] GAM160 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM160 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM160 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM160 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM160 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2190] The complementary binding of GAM160 RNA, herein designated GAM RNA, to target binding sites on GAM160 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM160 target RNA, herein designated GAM TARGET RNA, into GAM160 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2191] It is appreciated that GAM160 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM160 target genes. The mRNA of each one of this plurality of GAM160 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM160 RNA,

herein designated GAM RNA, and which when bound by GAM160 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM160 target proteins.

[2192] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM160 gene, herein designated GAM GENE, on one or more GAM160 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2193] It is yet further appreciated that specific functions, and accordingly utilities, of GAM160 correlate with, and may be deduced from, the identity of the target genes which

GAM160 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2194] Nucleotide sequences of the GAM160 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM160 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM160 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM160 are further described hereinbelow with reference to Table Table1.

[2195] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM160 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2196]

[2197] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 161 (GAM161) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2198] GAM161 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM161 was detected is described hereinabove with reference to Figs. 2-8.

[2199] GAM161 gene, herein designated GAM GENE, and GAM161 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2200] GAM161 gene, herein designated GAM GENE, encodes a GAM161 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM161 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM161 precursor RNA is designated SEQ ID:2295, and is provided hereinbelow with reference to the sequence listing part.

[2201] GAM161 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM161 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[2202] An enzyme complex designated DICER COMPLEX, dices the GAM161 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM161 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM161 RNA is designated SEQ ID:2296, and is provided hereinbelow with reference to the sequence listing part.

[2203] GAM161 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM161 target RNA, herein designated GAM TARGET RNA.
GAM161 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2204] GAM161 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM161 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM161 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM161 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM161 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2205] The complementary binding of GAM161 RNA, herein designated GAM RNA, to target binding sites on GAM161 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM161 target RNA, herein desig-

nated GAM TARGET RNA, into GAM161 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2206] It is appreciated that GAM161 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM161 target genes. The mRNA of each one of this plurality of GAM161 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM161 RNA, herein designated GAM RNA, and which when bound by GAM161 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM161 target proteins.

[2207] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM161 gene, herein designated GAM GENE, on one or more GAM161 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2208] It is yet further appreciated that specific functions, and accordingly utilities, of GAM161 correlate with, and may be deduced from, the identity of the target genes which GAM161 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2209] Nucleotide sequences of the GAM161 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM161 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM161 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM161 are further described hereinbelow with reference to Table Table1.

[2210] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM161 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[2211]

[2212] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 162 (GAM162) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2213] GAM162 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM162 was detected is described hereinabove with reference to Figs. 2-8.

[2214] GAM162 gene, herein designated GAM GENE, and GAM162 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2215] GAM162 gene, herein designated GAM GENE, encodes a GAM162 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM162 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM162 precursor RNA is designated SEQ ID:2312, and is provided hereinbelow with ref-

erence to the sequence listing part.

[2216] GAM162 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM162 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2217] An enzyme complex designated DICER COMPLEX, dices the GAM162 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM162 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 23%) nucleotide sequence of GAM162 RNA is designated SEQ ID:2313, and is provided hereinbelow with reference to the sequence listing part.

[2218] GAM162 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM162 target RNA, herein designated GAM TARGET RNA.

GAM162 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2219] GAM162 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM162 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM162 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM162 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM162 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2220] The complementary binding of GAM162 RNA, herein designated GAM RNA, to target binding sites on GAM162 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM162 target RNA, herein designated GAM TARGET RNA, into GAM162 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2221] It is appreciated that GAM162 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM162 target genes. The mRNA of each one of this plurality of GAM162 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM162 RNA, herein designated GAM RNA, and which when bound by GAM162 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM162 target proteins.

[2222] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM162 gene, herein designated GAM GENE, on one or more GAM162 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2223] It is yet further appreciated that specific functions, and accordingly utilities, of GAM162 correlate with, and may be deduced from, the identity of the target genes which GAM162 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2224] Nucleotide sequences of the GAM162 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM162 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM162 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM162 are further described hereinbelow with reference to Table Table1.

[2225] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM162 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2226]

[2227] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 163 (GAM163) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2228] GAM163 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM163 was detected is described hereinabove with reference to Figs. 2-8.

[2229] GAM163 gene, herein designated GAM GENE, and GAM163 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[2230] GAM163 gene, herein designated GAM GENE, encodes a GAM163 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM163 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM163 precursor RNA is designated SEQ ID:2328, and is provided hereinbelow with reference to the sequence listing part.

[2231] GAM163 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM163 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2232] An enzyme complex designated DICER COMPLEX, dices the GAM163 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM163 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 42%) nucleotide sequence of GAM163 RNA is designated SEQ ID:2329, and is provided hereinbelow with reference to the sequence listing part.

[2233] GAM163 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM163 target RNA, herein designated GAM TARGET RNA. GAM163 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2234] GAM163 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM163 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM163 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM163 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM163 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2235] The complementary binding of GAM163 RNA, herein designated GAM RNA, to target binding sites on GAM163 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM163 target RNA, herein designated GAM TARGET RNA, into GAM163 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2236] It is appreciated that GAM163 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM163 target genes. The mRNA of each one of this plurality of GAM163 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM163 RNA, herein designated GAM RNA, and which when bound by GAM163 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM163 target proteins.

[2237] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM163 gene, herein designated GAM GENE, on one or more GAM163 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[2238] It is yet further appreciated that specific functions, and accordingly utilities, of GAM163 correlate with, and may be deduced from, the identity of the target genes which GAM163 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2239] Nucleotide sequences of the GAM163 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM163 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM163 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM163 are further described hereinbelow with reference to Table Table1.

[2240] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM163 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2241]

[2242] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

164 (GAM164) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2243] GAM164 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM164 was detected is described hereinabove with reference to Figs. 2-8.

[2244] GAM164 gene, herein designated GAM GENE, and GAM164 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2245] GAM164 gene, herein designated GAM GENE, encodes a GAM164 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM164 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM164 precursor RNA is designated SEQ ID:2345, and is provided hereinbelow with reference to the sequence listing part.

[2246] GAM164 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM164 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2247] An enzyme complex designated DICER COMPLEX, dices the GAM164 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM164 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM164 RNA is designated SEQ ID:2346, and is provided hereinbelow with reference to the sequence listing part.

[2248] GAM164 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM164 target RNA, herein designated GAM TARGET RNA. GAM164 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2249] GAM164 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM164 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM164 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM164 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM164 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2250] The complementary binding of GAM164 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM164 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM164 target RNA, herein designated GAM TARGET RNA, into GAM164 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2251] It is appreciated that GAM164 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM164 target genes. The mRNA of each one of this plurality of GAM164 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM164 RNA, herein designated GAM RNA, and which when bound by GAM164 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM164 target proteins.

[2252] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM164 gene, herein designated GAM GENE, on one or more GAM164 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2253] It is yet further appreciated that specific functions, and accordingly utilities, of GAM164 correlate with, and may be deduced from, the identity of the target genes which GAM164 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2254] Nucleotide sequences of the GAM164 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM164 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM164 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM164 are further described hereinbelow with reference to Table Table1.

[2255] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM164 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2256]

[2257] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 165 (GAM165) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2258] GAM165 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM165 was detected is described hereinabove with reference to Figs. 2-8.

[2259] GAM165 gene, herein designated GAM GENE, and GAM165 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2260] GAM165 gene, herein designated GAM GENE, encodes a GAM165 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM165 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM165 precursor RNA is designated SEQ ID:2363, and is provided hereinbelow with reference to the sequence listing part.

[2261] GAM165 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM165 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2262] An enzyme complex designated DICER COMPLEX, dices the GAM165 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM165 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 64%) nucleotide sequence of GAM165 RNA is designated SEQ ID:2364, and is provided hereinbelow with reference to the sequence listing part.

[2263] GAM165 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM165 target RNA, herein designated GAM TARGET RNA. GAM165 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2264] GAM165 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM165 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM165 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM165 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM165 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2265] The complementary binding of GAM165 RNA, herein designated GAM RNA, to target binding sites on GAM165 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM165 target RNA, herein designated GAM TARGET RNA, into GAM165 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2266] It is appreciated that GAM165 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM165 target genes. The mRNA of each one of this plurality of GAM165 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM165 RNA, herein designated GAM RNA, and which when bound by

GAM165 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM165 target proteins.

[2267] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM165 gene, herein designated GAM GENE, on one or more GAM165 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2268] It is yet further appreciated that specific functions, and accordingly utilities, of GAM165 correlate with, and may be deduced from, the identity of the target genes which GAM165 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[2269] Nucleotide sequences of the GAM165 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM165 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM165 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM165 are further described hereinbelow with reference to Table Table1.

[2270] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM165 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2271]

[2272] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 166 (GAM166) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2273] GAM166 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM166 was detected is described hereinabove with reference to Figs. 2-8.

[2274] GAM166 gene, herein designated GAM GENE, and GAM166 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2275] GAM166 gene, herein designated GAM GENE, encodes a GAM166 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM166 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM166 precursor RNA is designated SEQ ID:2389, and is provided hereinbelow with reference to the sequence listing part.

[2276] GAM166 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM166 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[2277] An enzyme complex designated DICER COMPLEX, dices the GAM166 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM166 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 19%) nucleotide sequence of GAM166 RNA is designated SEQ ID:2390, and is provided hereinbelow with reference to the sequence listing part.

[2278] GAM166 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM166 target RNA, herein designated GAM TARGET RNA. GAM166 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2279] GAM166 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM166 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM166 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM166 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM166 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2280] The complementary binding of GAM166 RNA, herein designated GAM RNA, to target binding sites on GAM166 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM166 target RNA, herein designated GAM TARGET RNA, into GAM166 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2281] It is appreciated that GAM166 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM166 target genes. The mRNA of each one of this plurality of GAM166 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM166 RNA, herein designated GAM RNA, and which when bound by GAM166 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM166 target proteins.

[2282] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM166 gene, herein designated GAM GENE, on one or more GAM166 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2283] It is yet further appreciated that specific functions, and accordingly utilities, of GAM166 correlate with, and may be deduced from, the identity of the target genes which GAM166 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2284] Nucleotide sequences of the GAM166 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM166 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM166 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM166 are further described hereinbelow with reference to Table Table1.

[2285] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM166 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2286]

[2287] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 167 (GAM167) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2288] GAM167 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM167 was detected is described hereinabove with reference to Figs. 2-8.

[2289] GAM167 gene, herein designated GAM GENE, and GAM167 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2290] GAM167 gene, herein designated GAM GENE, encodes a GAM167 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM167 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM167 precursor RNA is designated SEQ ID:2400, and is provided hereinbelow with reference to the sequence listing part.

[2291] GAM167 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM167 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2292] An enzyme complex designated DICER COMPLEX, dices the GAM167 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM167 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 41%) nucleotide sequence of GAM167 RNA is designated SEQ ID:2401, and is provided hereinbelow with reference to the sequence listing part.

[2293] GAM167 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM167

target RNA, herein designated GAM TARGET RNA.

GAM167 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2294] GAM167 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM167 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM167 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM167 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM167 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2295] The complementary binding of GAM167 RNA, herein designated GAM RNA, to target binding sites on GAM167 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM167 target RNA, herein designated GAM TARGET RNA, into GAM167 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2296] It is appreciated that GAM167 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM167 target genes. The mRNA of each one of this plurality of GAM167 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM167 RNA, herein designated GAM RNA, and which when bound by GAM167 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM167 target proteins.

[2297] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM167 gene, herein designated GAM GENE, on one or more GAM167 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2298] It is yet further appreciated that specific functions, and accordingly utilities, of GAM167 correlate with, and may be deduced from, the identity of the target genes which GAM167 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2299] Nucleotide sequences of the GAM167 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM167 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM167 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM167 are further described hereinbelow with reference to Table Table1.

[2300] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM167 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2301]

[2302] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 168 (GAM168) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2303] GAM168 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM168 was detected is described hereinabove with reference to Figs. 2-8.

[2304] GAM168 gene, herein designated GAM GENE, and GAM168 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2305] GAM168 gene, herein designated GAM GENE, encodes a GAM168 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM168 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM168 precursor RNA is designated SEQ ID:2422, and is provided hereinbelow with reference to the sequence listing part.

[2306] GAM168 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM168 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2307] An enzyme complex designated DICER COMPLEX, dices the GAM168 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM168 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM168 RNA is designated SEQ ID:2423, and is provided hereinbelow with reference to the sequence listing part.

[2308] GAM168 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM168 target RNA, herein designated GAM TARGET RNA. GAM168 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2309] GAM168 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM168 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM168 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM168 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM168 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2310] The complementary binding of GAM168 RNA, herein designated GAM RNA, to target binding sites on GAM168 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM168 target RNA, herein designated GAM TARGET RNA, into GAM168 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2311] It is appreciated that GAM168 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM168 target genes. The mRNA of each one of this plu-

rality of GAM168 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM168 RNA, herein designated GAM RNA, and which when bound by GAM168 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM168 target proteins.

[2312] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM168 gene, herein designated GAM GENE, on one or more GAM168 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2313] It is yet further appreciated that specific functions, and accordingly utilities, of GAM168 correlate with, and may be deduced from, the identity of the target genes which GAM168 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2314] Nucleotide sequences of the GAM168 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM168 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM168 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM168 are further described hereinbelow with reference to Table Table1.

[2315] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM168 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2316]

[2317] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 169 (GAM169) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[2318] GAM169 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM169 was detected is described hereinabove with reference to Figs. 2-8.

[2319] GAM169 gene, herein designated GAM GENE, and GAM169 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2320] GAM169 gene, herein designated GAM GENE, encodes a GAM169 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM169 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM169 precursor RNA is designated SEQ ID:2434, and is provided hereinbelow with reference to the sequence listing part.

[2321] GAM169 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM169 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2322] An enzyme complex designated DICER COMPLEX, dices the GAM169 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM169 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 82%) nucleotide sequence of GAM169 RNA is designated SEQ ID:2435, and is provided hereinbelow with reference to the sequence listing part.

[2323] GAM169 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM169 target RNA, herein designated GAM TARGET RNA.

GAM169 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[2324] GAM169 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM169 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM169 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM169 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM169 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2325] The complementary binding of GAM169 RNA, herein designated GAM RNA, to target binding sites on GAM169 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM169 target RNA, herein designated GAM TARGET RNA, into GAM169 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2326] It is appreciated that GAM169 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM169 target genes. The mRNA of each one of this plurality of GAM169 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM169 RNA, herein designated GAM RNA, and which when bound by GAM169 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM169 target proteins.

[2327] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM169 gene, herein designated GAM GENE, on one or more GAM169 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2328] It is yet further appreciated that specific functions, and accordingly utilities, of GAM169 correlate with, and may be deduced from, the identity of the target genes which GAM169 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2329] Nucleotide sequences of the GAM169 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM169 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM169 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM169 are further described hereinbelow with reference to Table Table1.

[2330] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM169 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2331]

[2332] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 170 (GAM170) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2333] GAM170 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM170 was detected is described hereinabove with reference to Figs. 2-8.

[2334] GAM170 gene, herein designated GAM GENE, and GAM170 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2335] GAM170 gene, herein designated GAM GENE, encodes a GAM170 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM170 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM170 precursor RNA is designated SEQ ID:2448, and is provided hereinbelow with reference to the sequence listing part.

[2336] GAM170 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM170 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2337] An enzyme complex designated DICER COMPLEX, dices the GAM170 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM170 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of

GAM170 RNA is designated SEQ ID:2449, and is provided hereinbelow with reference to the sequence listing part.

[2338] GAM170 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM170 target RNA, herein designated GAM TARGET RNA. GAM170 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2339] GAM170 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM170 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM170 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM170 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM170 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2340] The complementary binding of GAM170 RNA, herein designated GAM RNA, to target binding sites on GAM170 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM170 target RNA, herein designated GAM TARGET RNA, into GAM170 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2341] It is appreciated that GAM170 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM170 target genes. The mRNA of each one of this plurality of GAM170 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM170 RNA, herein designated GAM RNA, and which when bound by GAM170 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM170 target proteins.

[2342] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM170 gene, herein designated GAM GENE, on one or more GAM170 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2343] It is yet further appreciated that specific functions, and accordingly utilities, of GAM170 correlate with, and may be deduced from, the identity of the target genes which GAM170 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2344] Nucleotide sequences of the GAM170 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM170 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM170 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM170 are further described hereinbelow with reference to Table Table1.

[2345] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM170 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2346]

[2347] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 171 (GAM171) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2348] GAM171 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM171 was detected is described hereinabove

with reference to Figs. 2-8.

[2349] GAM171 gene, herein designated GAM GENE, and GAM171 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2350] GAM171 gene, herein designated GAM GENE, encodes a GAM171 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM171 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM171 precursor RNA is designated SEQ ID:2458, and is provided hereinbelow with reference to the sequence listing part.

[2351] GAM171 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM171 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2352] An enzyme complex designated DICER COMPLEX, dices the GAM171 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM171 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM171 RNA is designated SEQ ID:2459, and is provided hereinbelow with reference to the sequence listing part.

[2353] GAM171 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM171 target RNA, herein designated GAM TARGET RNA. GAM171 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2354] GAM171 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM171 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM171 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM171 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM171 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2355] The complementary binding of GAM171 RNA, herein designated GAM RNA, to target binding sites on GAM171 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM171 target RNA, herein designated GAM TARGET RNA, into GAM171 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[2356] It is appreciated that GAM171 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM171 target genes. The mRNA of each one of this plurality of GAM171 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM171 RNA, herein designated GAM RNA, and which when bound by GAM171 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM171 target proteins.

[2357] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM171 gene, herein designated GAM GENE, on one or more GAM171 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2358] It is yet further appreciated that specific functions, and accordingly utilities, of GAM171 correlate with, and may be deduced from, the identity of the target genes which GAM171 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2359] Nucleotide sequences of the GAM171 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM171 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM171 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM171 are further described hereinbelow with reference to Table Table1.

[2360] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM171 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2361]

[2362] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 172 (GAM172) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2363] GAM172 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM172 was detected is described hereinabove with reference to Figs. 2-8.

[2364] GAM172 gene, herein designated GAM GENE, and GAM172 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2365] GAM172 gene, herein designated GAM GENE, encodes a GAM172 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM172 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM172 precursor RNA is designated SEQ ID:2477, and is provided hereinbelow with reference to the sequence listing part.

[2366] GAM172 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM172 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2367] An enzyme complex designated DICER COMPLEX, dices the GAM172 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM172 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM172 RNA is designated SEQ ID:2478, and is provided hereinbelow with reference to the sequence listing part.

[2368] GAM172 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM172 target RNA, herein designated GAM TARGET RNA.

GAM172 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2369] GAM172 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM172 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM172 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM172 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM172 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2370] The complementary binding of GAM172 RNA, herein designated GAM RNA, to target binding sites on GAM172 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM172 target RNA, herein designated GAM TARGET RNA, into GAM172 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2371] It is appreciated that GAM172 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM172 target genes. The mRNA of each one of this plurality of GAM172 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM172 RNA, herein designated GAM RNA, and which when bound by GAM172 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM172 target proteins.

[2372] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM172 gene, herein designated GAM GENE, on one or more GAM172 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2373] It is yet further appreciated that specific functions, and accordingly utilities, of GAM172 correlate with, and may be deduced from, the identity of the target genes which GAM172 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2374] Nucleotide sequences of the GAM172 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM172 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM172 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM172 are further described hereinbelow with reference to Table Table1.

[2375] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM172 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2376]

[2377] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 173 (GAM173) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2378] GAM173 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM173 was detected is described hereinabove with reference to Figs. 2-8.

[2379] GAM173 gene, herein designated GAM GENE, and GAM173 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2380] GAM173 gene, herein designated GAM GENE, encodes a

GAM173 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM173 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM173 precursor RNA is designated SEQ ID:2516, and is provided hereinbelow with reference to the sequence listing part.

[2381] GAM173 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM173 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2382] An enzyme complex designated DICER COMPLEX, dices the GAM173 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM173 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM173 RNA is designated SEQ ID:2517, and is provided hereinbelow with reference to the sequence listing part.

[2383] GAM173 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM173 target RNA, herein designated GAM TARGET RNA. GAM173 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2384] GAM173 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM173 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM173 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM173 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM173 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2385] The complementary binding of GAM173 RNA, herein designated GAM RNA, to target binding sites on GAM173 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM173 target RNA, herein designated GAM TARGET RNA, into GAM173 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2386] It is appreciated that GAM173 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM173 target genes. The mRNA of each one of this plurality of GAM173 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM173 RNA, herein designated GAM RNA, and which when bound by GAM173 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM173 target proteins.

[2387] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM173 gene, herein designated GAM GENE, on one or more GAM173 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2388] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM173 correlate with, and may be deduced from, the identity of the target genes which GAM173 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2389] Nucleotide sequences of the GAM173 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM173 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM173 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM173 are further described hereinbelow with reference to Table Table1.

[2390] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM173 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2391]

[2392] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 174 (GAM174) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[2393] GAM174 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM174 was detected is described hereinabove with reference to Figs. 2-8.

[2394] GAM174 gene, herein designated GAM GENE, and GAM174 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2395] GAM174 gene, herein designated GAM GENE, encodes a GAM174 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM174 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM174 precursor RNA is designated SEQ ID:2524, and is provided hereinbelow with reference to the sequence listing part.

[2396] GAM174 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM174 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2397] An enzyme complex designated DICER COMPLEX, dices the GAM174 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM174 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM174 RNA is designated SEQ ID:2525, and is provided hereinbelow with reference to the sequence listing part.

[2398] GAM174 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM174 target RNA, herein designated GAM TARGET RNA. GAM174 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2399] GAM174 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM174 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM174 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM174 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM174 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2400] The complementary binding of GAM174 RNA, herein designated GAM RNA, to target binding sites on GAM174 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM174 target RNA, herein designated GAM TARGET RNA, into GAM174 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2401] It is appreciated that GAM174 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM174 target genes. The mRNA of each one of this plurality of GAM174 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM174 RNA, herein designated GAM RNA, and which when bound by GAM174 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM174 target proteins.

[2402] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM174 gene, herein designated GAM GENE, on one or more GAM174 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2403] It is yet further appreciated that specific functions, and accordingly utilities, of GAM174 correlate with, and may be deduced from, the identity of the target genes which GAM174 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2404] Nucleotide sequences of the GAM174 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM174 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM174 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM174 are further described hereinbelow with reference to Table Table1.

[2405] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM174 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2406]

[2407] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 175 (GAM175) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2408] GAM175 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM175 was detected is described hereinabove with reference to Figs. 2-8.

[2409] GAM175 gene, herein designated GAM GENE, and GAM175 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2410] GAM175 gene, herein designated GAM GENE, encodes a GAM175 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM175 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM175 precursor RNA is designated SEQ ID:2532, and is provided hereinbelow with reference to the sequence listing part.

[2411] GAM175 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM175 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2412] An enzyme complex designated DICER COMPLEX, dices the GAM175 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM175 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM175 RNA is designated SEQ ID:2533, and is provided

hereinbelow with reference to the sequence listing part.

[2413] GAM175 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM175 target RNA, herein designated GAM TARGET RNA.
GAM175 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2414] GAM175 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM175 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM175 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM175 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM175 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2415] The complementary binding of GAM175 RNA, herein designated GAM RNA, to target binding sites on GAM175 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM175 target RNA, herein designated GAM TARGET RNA, into GAM175 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2416] It is appreciated that GAM175 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM175 target genes. The mRNA of each one of this plurality of GAM175 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM175 RNA, herein designated GAM RNA, and which when bound by GAM175 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM175 tar-

get proteins.

[2417] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM175 gene, herein designated GAM GENE, on one or more GAM175 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2418] It is yet further appreciated that specific functions, and accordingly utilities, of GAM175 correlate with, and may be deduced from, the identity of the target genes which GAM175 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2419] Nucleotide sequences of the GAM175 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM175 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM175 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM175 are further described hereinbelow with reference to Table Table1.

[2420] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM175 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2421]

[2422] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 176 (GAM176) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2423] GAM176 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM176 was detected is described hereinabove with reference to Figs. 2-8.

[2424] GAM176 gene, herein designated GAM GENE, and GAM176 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2425] GAM176 gene, herein designated GAM GENE, encodes a GAM176 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM176 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM176 precursor RNA is designated SEQ ID:2540, and is provided hereinbelow with reference to the sequence listing part.

[2426] GAM176 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM176 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2427] An enzyme complex designated DICER COMPLEX, dices

the GAM176 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM176 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM176 RNA is designated SEQ ID:2541, and is provided hereinbelow with reference to the sequence listing part.

[2428] GAM176 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM176 target RNA, herein designated GAM TARGET RNA. GAM176 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2429] GAM176 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM176 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM176

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM176 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM176 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2430] The complementary binding of GAM176 RNA, herein designated GAM RNA, to target binding sites on GAM176 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM176 target RNA, herein designated GAM TARGET RNA, into GAM176 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2431] It is appreciated that GAM176 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM176 target genes. The mRNA of each one of this plurality of GAM176 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM176 RNA, herein designated GAM RNA, and which when bound by GAM176 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM176 target proteins.

[2432] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM176 gene, herein designated GAM GENE, on one or more GAM176 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2433] It is yet further appreciated that specific functions, and accordingly utilities, of GAM176 correlate with, and may be deduced from, the identity of the target genes which GAM176 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2434] Nucleotide sequences of the GAM176 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM176 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM176 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM176 are further described hereinbelow with reference to Table Table1.

[2435] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM176 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2436]

[2437] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 177 (GAM177) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2438] GAM177 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM177 was detected is described hereinabove with reference to Figs. 2-8.

[2439] GAM177 gene, herein designated GAM GENE, and GAM177 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2440] GAM177 gene, herein designated GAM GENE, encodes a GAM177 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM177 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM177 precursor RNA is designated SEQ ID:2564, and is provided hereinbelow with reference to the sequence listing part.

[2441] GAM177 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM177 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2442] An enzyme complex designated DICER COMPLEX, dices the GAM177 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM177 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 35%) nucleotide sequence of GAM177 RNA is designated SEQ ID:2565, and is provided hereinbelow with reference to the sequence listing part.

[2443] GAM177 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM177 target RNA, herein designated GAM TARGET RNA. GAM177 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2444] GAM177 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM177 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM177 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM177 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM177 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[2445] The complementary binding of GAM177 RNA, herein designated GAM RNA, to target binding sites on GAM177 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM177 target RNA, herein designated GAM TARGET RNA, into GAM177 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2446] It is appreciated that GAM177 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM177 target genes. The mRNA of each one of this plurality of GAM177 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM177 RNA, herein designated GAM RNA, and which when bound by GAM177 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM177 target proteins.

[2447] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM177 gene, herein designated GAM GENE, on one or

more GAM177 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2448] It is yet further appreciated that specific functions, and accordingly utilities, of GAM177 correlate with, and may be deduced from, the identity of the target genes which GAM177 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2449] Nucleotide sequences of the GAM177 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM177 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM177 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM177 are further de-

scribed hereinbelow with reference to Table Table1.

[2450] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM177 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2451]

[2452] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 178 (GAM178) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2453] GAM178 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM178 was detected is described hereinabove with reference to Figs. 2-8.

[2454] GAM178 gene, herein designated GAM GENE, and GAM178 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2455] GAM178 gene, herein designated GAM GENE, encodes a GAM178 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM178 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM178 precursor RNA is designated SEQ ID:2583, and is provided hereinbelow with reference to the sequence listing part.

[2456] GAM178 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM178 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2457] An enzyme complex designated DICER COMPLEX, dices the GAM178 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM178 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM178 RNA is designated SEQ ID:2584, and is provided hereinbelow with reference to the sequence listing part.

[2458] GAM178 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM178 target RNA, herein designated GAM TARGET RNA. GAM178 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2459] GAM178 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM178 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM178 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM178 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM178 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2460] The complementary binding of GAM178 RNA, herein designated GAM RNA, to target binding sites on GAM178 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM178 target RNA, herein designated GAM TARGET RNA, into GAM178 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2461] It is appreciated that GAM178 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM178 target genes. The mRNA of each one of this plurality of GAM178 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM178 RNA, herein designated GAM RNA, and which when bound by GAM178 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM178 target proteins.

[2462] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM178 gene, herein designated GAM GENE, on one or more GAM178 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2463] It is yet further appreciated that specific functions, and accordingly utilities, of GAM178 correlate with, and may

be deduced from, the identity of the target genes which GAM178 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2464] Nucleotide sequences of the GAM178 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM178 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM178 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM178 are further described hereinbelow with reference to Table Table1.

[2465] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM178 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2466]

[2467] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 179 (GAM179) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2468] GAM179 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM179 was detected is described hereinabove with reference to Figs. 2-8.

[2469] GAM179 gene, herein designated GAM GENE, and GAM179 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2470] GAM179 gene, herein designated GAM GENE, encodes a GAM179 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM179 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM179 precursor RNA is designated SEQ ID:2595, and is provided hereinbelow with reference to the sequence listing part.

[2471] GAM179 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM179 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2472] An enzyme complex designated DICER COMPLEX, dices the GAM179 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM179 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 29%) nucleotide sequence of GAM179 RNA is designated SEQ ID:2596, and is provided hereinbelow with reference to the sequence listing part.

[2473] GAM179 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM179 target RNA, herein designated GAM TARGET RNA. GAM179 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2474] GAM179 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM179 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM179 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM179 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM179 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2475] The complementary binding of GAM179 RNA, herein designated GAM RNA, to target binding sites on GAM179 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM179 target RNA, herein designated GAM TARGET RNA, into GAM179 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2476] It is appreciated that GAM179 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM179 target genes. The mRNA of each one of this plurality of GAM179 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM179 RNA, herein designated GAM RNA, and which when bound by GAM179 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM179 target proteins.

[2477] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM179 gene, herein designated GAM GENE, on one or more GAM179 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2478] It is yet further appreciated that specific functions, and accordingly utilities, of GAM179 correlate with, and may be deduced from, the identity of the target genes which GAM179 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2479] Nucleotide sequences of the GAM179 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM179 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM179 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM179 are further described hereinbelow with reference to Table Table1.

[2480] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM179 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2481]

[2482] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 180 (GAM180) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2483] GAM180 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM180 was detected is described hereinabove with reference to Figs. 2-8.

[2484] GAM180 gene, herein designated GAM GENE, and GAM180 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2485] GAM180 gene, herein designated GAM GENE, encodes a GAM180 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM180 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM180 precursor RNA is desig-

nated SEQ ID:2600, and is provided hereinbelow with reference to the sequence listing part.

[2486] GAM180 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM180 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2487] An enzyme complex designated DICER COMPLEX, dices the GAM180 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM180 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 46%) nucleotide sequence of GAM180 RNA is designated SEQ ID:2601, and is provided hereinbelow with reference to the sequence listing part.

[2488] GAM180 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM180 target RNA, herein designated GAM TARGET RNA. GAM180 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2489] GAM180 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM180 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM180 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM180 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM180

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2490] The complementary binding of GAM180 RNA, herein designated GAM RNA, to target binding sites on GAM180 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM180 target RNA, herein designated GAM TARGET RNA, into GAM180 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2491] It is appreciated that GAM180 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM180 target genes. The mRNA of each one of this plurality of GAM180 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM180 RNA, herein designated GAM RNA, and which when bound by GAM180 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM180 target proteins.

[2492] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM180 gene, herein designated GAM GENE, on one or more GAM180 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2493] It is yet further appreciated that specific functions, and accordingly utilities, of GAM180 correlate with, and may be deduced from, the identity of the target genes which GAM180 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2494] Nucleotide sequences of the GAM180 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM180 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM180 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM180 are further described hereinbelow with reference to Table Table1.

[2495] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM180 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2496]

[2497] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 181 (GAM181) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2498] GAM181 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM181 was detected is described hereinabove with reference to Figs. 2-8.

[2499] GAM181 gene, herein designated GAM GENE, and

GAM181 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2500] GAM181 gene, herein designated GAM GENE, encodes a GAM181 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM181 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM181 precursor RNA is designated SEQ ID:2619, and is provided hereinbelow with reference to the sequence listing part.

[2501] GAM181 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM181 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2502] An enzyme complex designated DICER COMPLEX, dices the GAM181 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM181 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM181 RNA is designated SEQ ID:2620, and is provided hereinbelow with reference to the sequence listing part.

[2503] GAM181 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM181 target RNA, herein designated GAM TARGET RNA. GAM181 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2504] GAM181 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM181 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM181 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM181 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM181 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2505] The complementary binding of GAM181 RNA, herein designated GAM RNA, to target binding sites on GAM181 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM181 target RNA, herein designated GAM TARGET RNA, into GAM181 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2506] It is appreciated that GAM181 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM181 target genes. The mRNA of each one of this plurality of GAM181 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM181 RNA, herein designated GAM RNA, and which when bound by GAM181 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM181 target proteins.

[2507] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM181 gene, herein designated GAM GENE, on one or more GAM181 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2508] It is yet further appreciated that specific functions, and accordingly utilities, of GAM181 correlate with, and may be deduced from, the identity of the target genes which GAM181 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2509] Nucleotide sequences of the GAM181 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM181 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM181 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM181 are further described hereinbelow with reference to Table Table1.

[2510] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM181 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2511]

[2512] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 182 (GAM182) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2513] GAM182 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM182 was detected is described hereinabove with reference to Figs. 2-8.

[2514] GAM182 gene, herein designated GAM GENE, and GAM182 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2515] GAM182 gene, herein designated GAM GENE, encodes a GAM182 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM182 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM182 precursor RNA is designated SEQ ID:2643, and is provided hereinbelow with reference to the sequence listing part.

[2516] GAM182 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM182 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2517] An enzyme complex designated DICER COMPLEX, dices the GAM182 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM182 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM182 RNA is designated SEQ ID:2644, and is provided hereinbelow with reference to the sequence listing part.

[2518] GAM182 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM182 target RNA, herein designated GAM TARGET RNA. GAM182 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2519] GAM182 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM182 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM182 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM182 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM182 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2520] The complementary binding of GAM182 RNA, herein designated GAM RNA, to target binding sites on GAM182 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM182 target RNA, herein designated GAM TARGET RNA, into GAM182 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2521] It is appreciated that GAM182 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM182 target genes. The mRNA of each one of this plurality of GAM182 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM182 RNA, herein designated GAM RNA, and which when bound by GAM182 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM182 target proteins.

[2522] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM182 gene, herein designated GAM GENE, on one or more GAM182 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2523] It is yet further appreciated that specific functions, and accordingly utilities, of GAM182 correlate with, and may be deduced from, the identity of the target genes which GAM182 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2524] Nucleotide sequences of the GAM182 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM182 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM182 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM182 are further described hereinbelow with reference to Table Table1.

[2525] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM182 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2526]

[2527] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 183 (GAM183) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2528] GAM183 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM183 was detected is described hereinabove with reference to Figs. 2-8.

[2529] GAM183 gene, herein designated GAM GENE, and GAM183 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2530] GAM183 gene, herein designated GAM GENE, encodes a GAM183 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM183 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM183 precursor RNA is designated SEQ ID:2666, and is provided hereinbelow with reference to the sequence listing part.

[2531] GAM183 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM183 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2532] An enzyme complex designated DICER COMPLEX, dices the GAM183 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM183 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 32%) nucleotide sequence of GAM183 RNA is designated SEQ ID:2667, and is provided hereinbelow with reference to the sequence listing part.

[2533] GAM183 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM183 target RNA, herein designated GAM TARGET RNA. GAM183 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2534] GAM183 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM183 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM183 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM183 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM183 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2535] The complementary binding of GAM183 RNA, herein designated GAM RNA, to target binding sites on GAM183 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM183 target RNA, herein designated GAM TARGET RNA, into GAM183 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2536] It is appreciated that GAM183 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM183 target genes. The mRNA of each one of this plurality of GAM183 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM183 RNA,

herein designated GAM RNA, and which when bound by GAM183 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM183 target proteins.

[2537] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM183 gene, herein designated GAM GENE, on one or more GAM183 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2538] It is yet further appreciated that specific functions, and accordingly utilities, of GAM183 correlate with, and may be deduced from, the identity of the target genes which

GAM183 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2539] Nucleotide sequences of the GAM183 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM183 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM183 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM183 are further described hereinbelow with reference to Table Table1.

[2540] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM183 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2541]

[2542] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 184 (GAM184) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2543] GAM184 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM184 was detected is described hereinabove with reference to Figs. 2-8.

[2544] GAM184 gene, herein designated GAM GENE, and GAM184 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2545] GAM184 gene, herein designated GAM GENE, encodes a GAM184 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM184 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM184 precursor RNA is designated SEQ ID:2682, and is provided hereinbelow with reference to the sequence listing part.

[2546] GAM184 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM184 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[2547] An enzyme complex designated DICER COMPLEX, dices the GAM184 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM184 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM184 RNA is designated SEQ ID:2683, and is provided hereinbelow with reference to the sequence listing part.

[2548] GAM184 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM184 target RNA, herein designated GAM TARGET RNA.
GAM184 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2549] GAM184 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM184 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM184 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM184 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM184 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2550] The complementary binding of GAM184 RNA, herein designated GAM RNA, to target binding sites on GAM184 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM184 target RNA, herein desig-

nated GAM TARGET RNA, into GAM184 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2551] It is appreciated that GAM184 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM184 target genes. The mRNA of each one of this plurality of GAM184 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM184 RNA, herein designated GAM RNA, and which when bound by GAM184 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM184 target proteins.

[2552] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM184 gene, herein designated GAM GENE, on one or more GAM184 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2553] It is yet further appreciated that specific functions, and accordingly utilities, of GAM184 correlate with, and may be deduced from, the identity of the target genes which GAM184 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2554] Nucleotide sequences of the GAM184 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM184 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM184 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM184 are further described hereinbelow with reference to Table Table1.

[2555] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM184 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[2556]

[2557] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 185 (GAM185) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2558] GAM185 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM185 was detected is described hereinabove with reference to Figs. 2-8.

[2559] GAM185 gene, herein designated GAM GENE, and GAM185 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2560] GAM185 gene, herein designated GAM GENE, encodes a GAM185 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM185 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM185 precursor RNA is designated SEQ ID:2692, and is provided hereinbelow with ref-

erence to the sequence listing part.

[2561] GAM185 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM185 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2562] An enzyme complex designated DICER COMPLEX, dices the GAM185 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM185 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM185 RNA is designated SEQ ID:2693, and is provided hereinbelow with reference to the sequence listing part.

[2563] GAM185 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM185 target RNA, herein designated GAM TARGET RNA.

GAM185 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2564] GAM185 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM185 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM185 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM185 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM185 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2565] The complementary binding of GAM185 RNA, herein designated GAM RNA, to target binding sites on GAM185 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM185 target RNA, herein designated GAM TARGET RNA, into GAM185 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2566] It is appreciated that GAM185 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM185 target genes. The mRNA of each one of this plurality of GAM185 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM185 RNA, herein designated GAM RNA, and which when bound by GAM185 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM185 target proteins.

[2567] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM185 gene, herein designated GAM GENE, on one or more GAM185 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2568] It is yet further appreciated that specific functions, and accordingly utilities, of GAM185 correlate with, and may be deduced from, the identity of the target genes which GAM185 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2569] Nucleotide sequences of the GAM185 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM185 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM185 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM185 are further described hereinbelow with reference to Table Table1.

[2570] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM185 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2571]

[2572] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 186 (GAM186) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2573] GAM186 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM186 was detected is described hereinabove with reference to Figs. 2-8.

[2574] GAM186 gene, herein designated GAM GENE, and GAM186 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[2575] GAM186 gene, herein designated GAM GENE, encodes a GAM186 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM186 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM186 precursor RNA is designated SEQ ID:2706, and is provided hereinbelow with reference to the sequence listing part.

[2576] GAM186 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM186 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2577] An enzyme complex designated DICER COMPLEX, dices the GAM186 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM186 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM186 RNA is designated SEQ ID:2707, and is provided hereinbelow with reference to the sequence listing part.

[2578] GAM186 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM186 target RNA, herein designated GAM TARGET RNA. GAM186 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2579] GAM186 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM186 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM186 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM186 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM186 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2580] The complementary binding of GAM186 RNA, herein designated GAM RNA, to target binding sites on GAM186 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM186 target RNA, herein designated GAM TARGET RNA, into GAM186 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2581] It is appreciated that GAM186 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM186 target genes. The mRNA of each one of this plurality of GAM186 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM186 RNA, herein designated GAM RNA, and which when bound by GAM186 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM186 target proteins.

[2582] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM186 gene, herein designated GAM GENE, on one or more GAM186 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[2583] It is yet further appreciated that specific functions, and accordingly utilities, of GAM186 correlate with, and may be deduced from, the identity of the target genes which GAM186 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2584] Nucleotide sequences of the GAM186 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM186 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM186 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM186 are further described hereinbelow with reference to Table Table1.

[2585] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM186 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2586]

[2587] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

187 (GAM187) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2588] GAM187 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM187 was detected is described hereinabove with reference to Figs. 2-8.

[2589] GAM187 gene, herein designated GAM GENE, and GAM187 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2590] GAM187 gene, herein designated GAM GENE, encodes a GAM187 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM187 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM187 precursor RNA is designated SEQ ID:2715, and is provided hereinbelow with reference to the sequence listing part.

[2591] GAM187 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM187 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2592] An enzyme complex designated DICER COMPLEX, dices the GAM187 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM187 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM187 RNA is designated SEQ ID:2716, and is provided hereinbelow with reference to the sequence listing part.

[2593] GAM187 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM187 target RNA, herein designated GAM TARGET RNA. GAM187 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2594] GAM187 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM187 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM187 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM187 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM187 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2595] The complementary binding of GAM187 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM187 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM187 target RNA, herein designated GAM TARGET RNA, into GAM187 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2596] It is appreciated that GAM187 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM187 target genes. The mRNA of each one of this plurality of GAM187 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM187 RNA, herein designated GAM RNA, and which when bound by GAM187 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM187 target proteins.

[2597] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM187 gene, herein designated GAM GENE, on one or more GAM187 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2598] It is yet further appreciated that specific functions, and accordingly utilities, of GAM187 correlate with, and may be deduced from, the identity of the target genes which GAM187 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2599] Nucleotide sequences of the GAM187 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM187 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM187 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM187 are further described hereinbelow with reference to Table Table1.

[2600] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM187 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2601]

[2602] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 188 (GAM188) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2603] GAM188 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM188 was detected is described hereinabove with reference to Figs. 2-8.

[2604] GAM188 gene, herein designated GAM GENE, and GAM188 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2605] GAM188 gene, herein designated GAM GENE, encodes a GAM188 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM188 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM188 precursor RNA is designated SEQ ID:2734, and is provided hereinbelow with reference to the sequence listing part.

[2606] GAM188 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM188 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2607] An enzyme complex designated DICER COMPLEX, dices the GAM188 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM188 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 61%) nucleotide sequence of GAM188 RNA is designated SEQ ID:2735, and is provided hereinbelow with reference to the sequence listing part.

[2608] GAM188 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM188 target RNA, herein designated GAM TARGET RNA. GAM188 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2609] GAM188 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM188 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM188 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM188 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM188 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2610] The complementary binding of GAM188 RNA, herein designated GAM RNA, to target binding sites on GAM188 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM188 target RNA, herein designated GAM TARGET RNA, into GAM188 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2611] It is appreciated that GAM188 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM188 target genes. The mRNA of each one of this plurality of GAM188 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM188 RNA, herein designated GAM RNA, and which when bound by

GAM188 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM188 target proteins.

[2612] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM188 gene, herein designated GAM GENE, on one or more GAM188 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2613] It is yet further appreciated that specific functions, and accordingly utilities, of GAM188 correlate with, and may be deduced from, the identity of the target genes which GAM188 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[2614] Nucleotide sequences of the GAM188 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM188 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM188 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM188 are further described hereinbelow with reference to Table Table1.

[2615] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM188 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2616]

[2617] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 189 (GAM189) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2618] GAM189 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM189 was detected is described hereinabove with reference to Figs. 2-8.

[2619] GAM189 gene, herein designated GAM GENE, and GAM189 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2620] GAM189 gene, herein designated GAM GENE, encodes a GAM189 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM189 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM189 precursor RNA is designated SEQ ID:2737, and is provided hereinbelow with reference to the sequence listing part.

[2621] GAM189 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM189 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[2622] An enzyme complex designated DICER COMPLEX, dices the GAM189 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM189 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM189 RNA is designated SEQ ID:2738, and is provided hereinbelow with reference to the sequence listing part.

[2623] GAM189 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM189 target RNA, herein designated GAM TARGET RNA. GAM189 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2624] GAM189 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM189 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM189 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM189 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM189 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2625] The complementary binding of GAM189 RNA, herein designated GAM RNA, to target binding sites on GAM189 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM189 target RNA, herein designated GAM TARGET RNA, into GAM189 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2626] It is appreciated that GAM189 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM189 target genes. The mRNA of each one of this plurality of GAM189 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM189 RNA, herein designated GAM RNA, and which when bound by GAM189 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM189 target proteins.

[2627] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM189 gene, herein designated GAM GENE, on one or more GAM189 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2628] It is yet further appreciated that specific functions, and accordingly utilities, of GAM189 correlate with, and may be deduced from, the identity of the target genes which GAM189 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2629] Nucleotide sequences of the GAM189 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM189 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM189 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM189 are further described hereinbelow with reference to Table Table1.

[2630] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM189 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2631]

[2632] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 190 (GAM190) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2633] GAM190 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM190 was detected is described hereinabove with reference to Figs. 2-8.

[2634] GAM190 gene, herein designated GAM GENE, and GAM190 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2635] GAM190 gene, herein designated GAM GENE, encodes a GAM190 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM190 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM190 precursor RNA is designated SEQ ID:2744, and is provided hereinbelow with reference to the sequence listing part.

[2636] GAM190 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM190 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2637] An enzyme complex designated DICER COMPLEX, dices the GAM190 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM190 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM190 RNA is designated SEQ ID:2745, and is provided hereinbelow with reference to the sequence listing part.

[2638] GAM190 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM190

target RNA, herein designated GAM TARGET RNA.

GAM190 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2639] GAM190 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM190 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM190 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM190 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM190 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2640] The complementary binding of GAM190 RNA, herein designated GAM RNA, to target binding sites on GAM190 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM190 target RNA, herein designated GAM TARGET RNA, into GAM190 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2641] It is appreciated that GAM190 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM190 target genes. The mRNA of each one of this plurality of GAM190 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM190 RNA, herein designated GAM RNA, and which when bound by GAM190 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM190 target proteins.

[2642] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM190 gene, herein designated GAM GENE, on one or more GAM190 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2643] It is yet further appreciated that specific functions, and accordingly utilities, of GAM190 correlate with, and may be deduced from, the identity of the target genes which GAM190 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2644] Nucleotide sequences of the GAM190 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM190 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM190 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM190 are further described hereinbelow with reference to Table Table1.

[2645] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM190 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2646]

[2647] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 191 (GAM191) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2648] GAM191 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM191 was detected is described hereinabove with reference to Figs. 2-8.

[2649] GAM191 gene, herein designated GAM GENE, and GAM191 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2650] GAM191 gene, herein designated GAM GENE, encodes a GAM191 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM191 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM191 precursor RNA is designated SEQ ID:2753, and is provided hereinbelow with reference to the sequence listing part.

[2651] GAM191 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM191 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2652] An enzyme complex designated DICER COMPLEX, dices the GAM191 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM191 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM191 RNA is designated SEQ ID:2754, and is provided hereinbelow with reference to the sequence listing part.

[2653] GAM191 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM191 target RNA, herein designated GAM TARGET RNA. GAM191 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2654] GAM191 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM191 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM191 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM191 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM191 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2655] The complementary binding of GAM191 RNA, herein designated GAM RNA, to target binding sites on GAM191 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM191 target RNA, herein designated GAM TARGET RNA, into GAM191 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2656] It is appreciated that GAM191 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM191 target genes. The mRNA of each one of this plu-

rality of GAM191 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM191 RNA, herein designated GAM RNA, and which when bound by GAM191 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM191 target proteins.

[2657] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM191 gene, herein designated GAM GENE, on one or more GAM191 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2658] It is yet further appreciated that specific functions, and accordingly utilities, of GAM191 correlate with, and may be deduced from, the identity of the target genes which GAM191 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2659] Nucleotide sequences of the GAM191 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM191 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM191 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM191 are further described hereinbelow with reference to Table Table1.

[2660] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM191 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2661]

[2662] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 192 (GAM192) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[2663] GAM192 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM192 was detected is described hereinabove with reference to Figs. 2-8.

[2664] GAM192 gene, herein designated GAM GENE, and GAM192 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2665] GAM192 gene, herein designated GAM GENE, encodes a GAM192 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM192 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM192 precursor RNA is designated SEQ ID:2763, and is provided hereinbelow with reference to the sequence listing part.

[2666] GAM192 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM192 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2667] An enzyme complex designated DICER COMPLEX, dices the GAM192 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM192 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM192 RNA is designated SEQ ID:2764, and is provided hereinbelow with reference to the sequence listing part.

[2668] GAM192 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM192 target RNA, herein designated GAM TARGET RNA.

GAM192 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[2669] GAM192 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM192 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM192 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM192 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM192 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2670] The complementary binding of GAM192 RNA, herein designated GAM RNA, to target binding sites on GAM192 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM192 target RNA, herein designated GAM TARGET RNA, into GAM192 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2671] It is appreciated that GAM192 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM192 target genes. The mRNA of each one of this plurality of GAM192 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM192 RNA, herein designated GAM RNA, and which when bound by GAM192 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM192 target proteins.

[2672] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM192 gene, herein designated GAM GENE, on one or more GAM192 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2673] It is yet further appreciated that specific functions, and accordingly utilities, of GAM192 correlate with, and may be deduced from, the identity of the target genes which GAM192 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2674] Nucleotide sequences of the GAM192 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM192 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM192 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM192 are further described hereinbelow with reference to Table Table1.

[2675] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM192 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2676]

[2677] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 193 (GAM193) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2678] GAM193 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM193 was detected is described hereinabove with reference to Figs. 2-8.

[2679] GAM193 gene, herein designated GAM GENE, and GAM193 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2680] GAM193 gene, herein designated GAM GENE, encodes a GAM193 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM193 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM193 precursor RNA is designated SEQ ID:2783, and is provided hereinbelow with reference to the sequence listing part.

[2681] GAM193 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM193 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2682] An enzyme complex designated DICER COMPLEX, dices the GAM193 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM193 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of

GAM193 RNA is designated SEQ ID:2784, and is provided hereinbelow with reference to the sequence listing part.

[2683] GAM193 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM193 target RNA, herein designated GAM TARGET RNA.

GAM193 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2684] GAM193 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM193 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM193 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM193 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM193 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2685] The complementary binding of GAM193 RNA, herein designated GAM RNA, to target binding sites on GAM193 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM193 target RNA, herein designated GAM TARGET RNA, into GAM193 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2686] It is appreciated that GAM193 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM193 target genes. The mRNA of each one of this plurality of GAM193 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM193 RNA, herein designated GAM RNA, and which when bound by GAM193 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM193 target proteins.

[2687] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM193 gene, herein designated GAM GENE, on one or more GAM193 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2688] It is yet further appreciated that specific functions, and accordingly utilities, of GAM193 correlate with, and may be deduced from, the identity of the target genes which GAM193 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2689] Nucleotide sequences of the GAM193 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM193 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM193 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM193 are further described hereinbelow with reference to Table Table1.

[2690] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM193 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2691]

[2692] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 194 (GAM194) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2693] GAM194 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM194 was detected is described hereinabove

with reference to Figs. 2-8.

[2694] GAM194 gene, herein designated GAM GENE, and GAM194 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2695] GAM194 gene, herein designated GAM GENE, encodes a GAM194 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM194 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM194 precursor RNA is designated SEQ ID:2794, and is provided hereinbelow with reference to the sequence listing part.

[2696] GAM194 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM194 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2697] An enzyme complex designated DICER COMPLEX, dices the GAM194 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM194 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM194 RNA is designated SEQ ID:2795, and is provided hereinbelow with reference to the sequence listing part.

[2698] GAM194 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM194 target RNA, herein designated GAM TARGET RNA. GAM194 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2699] GAM194 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM194 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM194 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM194 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM194 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2700] The complementary binding of GAM194 RNA, herein designated GAM RNA, to target binding sites on GAM194 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM194 target RNA, herein designated GAM TARGET RNA, into GAM194 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[2701] It is appreciated that GAM194 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM194 target genes. The mRNA of each one of this plurality of GAM194 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM194 RNA, herein designated GAM RNA, and which when bound by GAM194 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM194 target proteins.

[2702] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM194 gene, herein designated GAM GENE, on one or more GAM194 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2703] It is yet further appreciated that specific functions, and accordingly utilities, of GAM194 correlate with, and may be deduced from, the identity of the target genes which GAM194 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2704] Nucleotide sequences of the GAM194 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM194 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM194 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM194 are further described hereinbelow with reference to Table Table1.

[2705] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM194 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2706]

[2707] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 195 (GAM195) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2708] GAM195 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM195 was detected is described hereinabove with reference to Figs. 2-8.

[2709] GAM195 gene, herein designated GAM GENE, and GAM195 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2710] GAM195 gene, herein designated GAM GENE, encodes a GAM195 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM195 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM195 precursor RNA is designated SEQ ID:2807, and is provided hereinbelow with reference to the sequence listing part.

[2711] GAM195 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM195 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2712] An enzyme complex designated DICER COMPLEX, dices the GAM195 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM195 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM195 RNA is designated SEQ ID:2808, and is provided hereinbelow with reference to the sequence listing part.

[2713] GAM195 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM195 target RNA, herein designated GAM TARGET RNA.

GAM195 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2714] GAM195 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM195 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM195 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM195 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM195 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2715] The complementary binding of GAM195 RNA, herein designated GAM RNA, to target binding sites on GAM195 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM195 target RNA, herein designated GAM TARGET RNA, into GAM195 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2716] It is appreciated that GAM195 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM195 target genes. The mRNA of each one of this plurality of GAM195 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM195 RNA, herein designated GAM RNA, and which when bound by GAM195 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM195 target proteins.

[2717] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM195 gene, herein designated GAM GENE, on one or more GAM195 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2718] It is yet further appreciated that specific functions, and accordingly utilities, of GAM195 correlate with, and may be deduced from, the identity of the target genes which GAM195 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2719] Nucleotide sequences of the GAM195 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM195 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM195 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM195 are further described hereinbelow with reference to Table Table1.

[2720] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM195 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2721]

[2722] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 196 (GAM196) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2723] GAM196 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM196 was detected is described hereinabove with reference to Figs. 2-8.

[2724] GAM196 gene, herein designated GAM GENE, and GAM196 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2725] GAM196 gene, herein designated GAM GENE, encodes a

GAM196 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM196 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM196 precursor RNA is designated SEQ ID:2826, and is provided hereinbelow with reference to the sequence listing part.

[2726] GAM196 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM196 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2727] An enzyme complex designated DICER COMPLEX, dices the GAM196 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM196 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM196 RNA is designated SEQ ID:2827, and is provided hereinbelow with reference to the sequence listing part.

[2728] GAM196 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM196 target RNA, herein designated GAM TARGET RNA. GAM196 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2729] GAM196 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM196 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM196 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM196 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM196 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2730] The complementary binding of GAM196 RNA, herein designated GAM RNA, to target binding sites on GAM196 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM196 target RNA, herein designated GAM TARGET RNA, into GAM196 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2731] It is appreciated that GAM196 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM196 target genes. The mRNA of each one of this plurality of GAM196 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM196 RNA, herein designated GAM RNA, and which when bound by GAM196 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM196 target proteins.

[2732] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM196 gene, herein designated GAM GENE, on one or more GAM196 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2733] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM196 correlate with, and may be deduced from, the identity of the target genes which GAM196 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2734] Nucleotide sequences of the GAM196 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM196 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM196 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM196 are further described hereinbelow with reference to Table Table1.

[2735] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM196 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2736]

[2737] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 197 (GAM197) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[2738] GAM197 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM197 was detected is described hereinabove with reference to Figs. 2-8.

[2739] GAM197 gene, herein designated GAM GENE, and GAM197 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2740] GAM197 gene, herein designated GAM GENE, encodes a GAM197 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM197 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM197 precursor RNA is designated SEQ ID:2846, and is provided hereinbelow with reference to the sequence listing part.

[2741] GAM197 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM197 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2742] An enzyme complex designated DICER COMPLEX, dices the GAM197 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM197 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM197 RNA is designated SEQ ID:2847, and is provided hereinbelow with reference to the sequence listing part.

[2743] GAM197 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM197 target RNA, herein designated GAM TARGET RNA. GAM197 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2744] GAM197 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM197 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM197 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM197 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM197 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2745] The complementary binding of GAM197 RNA, herein designated GAM RNA, to target binding sites on GAM197 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM197 target RNA, herein designated GAM TARGET RNA, into GAM197 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2746] It is appreciated that GAM197 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM197 target genes. The mRNA of each one of this plurality of GAM197 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM197 RNA, herein designated GAM RNA, and which when bound by GAM197 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM197 target proteins.

[2747] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM197 gene, herein designated GAM GENE, on one or more GAM197 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2748] It is yet further appreciated that specific functions, and accordingly utilities, of GAM197 correlate with, and may be deduced from, the identity of the target genes which GAM197 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2749] Nucleotide sequences of the GAM197 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM197 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM197 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM197 are further described hereinbelow with reference to Table Table1.

[2750] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM197 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2751]

[2752] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 198 (GAM198) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2753] GAM198 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM198 was detected is described hereinabove with reference to Figs. 2-8.

[2754] GAM198 gene, herein designated GAM GENE, and GAM198 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2755] GAM198 gene, herein designated GAM GENE, encodes a GAM198 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM198 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM198 precursor RNA is designated SEQ ID:2858, and is provided hereinbelow with reference to the sequence listing part.

[2756] GAM198 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM198 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2757] An enzyme complex designated DICER COMPLEX, dices the GAM198 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM198 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM198 RNA is designated SEQ ID:2859, and is provided

hereinbelow with reference to the sequence listing part.

[2758] GAM198 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM198 target RNA, herein designated GAM TARGET RNA.

GAM198 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2759] GAM198 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM198 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM198 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM198 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM198 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2760] The complementary binding of GAM198 RNA, herein designated GAM RNA, to target binding sites on GAM198 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM198 target RNA, herein designated GAM TARGET RNA, into GAM198 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2761] It is appreciated that GAM198 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM198 target genes. The mRNA of each one of this plurality of GAM198 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM198 RNA, herein designated GAM RNA, and which when bound by GAM198 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM198 tar-

get proteins.

[2762] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM198 gene, herein designated GAM GENE, on one or more GAM198 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2763] It is yet further appreciated that specific functions, and accordingly utilities, of GAM198 correlate with, and may be deduced from, the identity of the target genes which GAM198 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2764] Nucleotide sequences of the GAM198 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM198 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM198 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM198 are further described hereinbelow with reference to Table Table1.

[2765] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM198 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2766]

[2767] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 199 (GAM199) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2768] GAM199 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM199 was detected is described hereinabove with reference to Figs. 2-8.

[2769] GAM199 gene, herein designated GAM GENE, and GAM199 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2770] GAM199 gene, herein designated GAM GENE, encodes a GAM199 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM199 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM199 precursor RNA is designated SEQ ID:2874, and is provided hereinbelow with reference to the sequence listing part.

[2771] GAM199 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM199 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2772] An enzyme complex designated DICER COMPLEX, dices

the GAM199 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM199 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 42%) nucleotide sequence of GAM199 RNA is designated SEQ ID:2875, and is provided hereinbelow with reference to the sequence listing part.

[2773] GAM199 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM199 target RNA, herein designated GAM TARGET RNA. GAM199 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2774] GAM199 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM199 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM199

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM199 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM199 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2775] The complementary binding of GAM199 RNA, herein designated GAM RNA, to target binding sites on GAM199 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM199 target RNA, herein designated GAM TARGET RNA, into GAM199 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2776] It is appreciated that GAM199 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM199 target genes. The mRNA of each one of this plurality of GAM199 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM199 RNA, herein designated GAM RNA, and which when bound by GAM199 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM199 target proteins.

[2777] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM199 gene, herein designated GAM GENE, on one or more GAM199 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2778] It is yet further appreciated that specific functions, and accordingly utilities, of GAM199 correlate with, and may be deduced from, the identity of the target genes which GAM199 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2779] Nucleotide sequences of the GAM199 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM199 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM199 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM199 are further described hereinbelow with reference to Table Table1.

[2780] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM199 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2781]

[2782] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 200 (GAM200) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2783] GAM200 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM200 was detected is described hereinabove with reference to Figs. 2-8.

[2784] GAM200 gene, herein designated GAM GENE, and GAM200 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2785] GAM200 gene, herein designated GAM GENE, encodes a GAM200 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM200 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM200 precursor RNA is designated SEQ ID:2880, and is provided hereinbelow with reference to the sequence listing part.

[2786] GAM200 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM200 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2787] An enzyme complex designated DICER COMPLEX, dices the GAM200 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM200 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 20%) nucleotide sequence of GAM200 RNA is designated SEQ ID:2881, and is provided hereinbelow with reference to the sequence listing part.

[2788] GAM200 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM200 target RNA, herein designated GAM TARGET RNA. GAM200 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2789] GAM200 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM200 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM200 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM200 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM200 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[2790] The complementary binding of GAM200 RNA, herein designated GAM RNA, to target binding sites on GAM200 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM200 target RNA, herein designated GAM TARGET RNA, into GAM200 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2791] It is appreciated that GAM200 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM200 target genes. The mRNA of each one of this plurality of GAM200 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM200 RNA, herein designated GAM RNA, and which when bound by GAM200 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM200 target proteins.

[2792] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM200 gene, herein designated GAM GENE, on one or

more GAM200 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2793] It is yet further appreciated that specific functions, and accordingly utilities, of GAM200 correlate with, and may be deduced from, the identity of the target genes which GAM200 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2794] Nucleotide sequences of the GAM200 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM200 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM200 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM200 are further de-

scribed hereinbelow with reference to Table Table1.

[2795] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM200 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2796]

[2797] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 201 (GAM201) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2798] GAM201 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM201 was detected is described hereinabove with reference to Figs. 2-8.

[2799] GAM201 gene, herein designated GAM GENE, and GAM201 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2800] GAM201 gene, herein designated GAM GENE, encodes a GAM201 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM201 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM201 precursor RNA is designated SEQ ID:2898, and is provided hereinbelow with reference to the sequence listing part.

[2801] GAM201 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM201 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2802] An enzyme complex designated DICER COMPLEX, dices the GAM201 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM201 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM201 RNA is designated SEQ ID:2899, and is provided hereinbelow with reference to the sequence listing part.

[2803] GAM201 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM201 target RNA, herein designated GAM TARGET RNA. GAM201 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2804] GAM201 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM201 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM201 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM201 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM201 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2805] The complementary binding of GAM201 RNA, herein designated GAM RNA, to target binding sites on GAM201 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM201 target RNA, herein designated GAM TARGET RNA, into GAM201 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2806] It is appreciated that GAM201 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM201 target genes. The mRNA of each one of this plurality of GAM201 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM201 RNA, herein designated GAM RNA, and which when bound by GAM201 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM201 target proteins.

[2807] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM201 gene, herein designated GAM GENE, on one or more GAM201 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2808] It is yet further appreciated that specific functions, and accordingly utilities, of GAM201 correlate with, and may

be deduced from, the identity of the target genes which GAM201 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2809] Nucleotide sequences of the GAM201 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM201 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM201 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM201 are further described hereinbelow with reference to Table Table1.

[2810] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM201 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2811]

[2812] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 202 (GAM202) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2813] GAM202 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM202 was detected is described hereinabove with reference to Figs. 2-8.

[2814] GAM202 gene, herein designated GAM GENE, and GAM202 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2815] GAM202 gene, herein designated GAM GENE, encodes a GAM202 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM202 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM202 precursor RNA is designated SEQ ID:2921, and is provided hereinbelow with reference to the sequence listing part.

[2816] GAM202 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM202 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2817] An enzyme complex designated DICER COMPLEX, dices the GAM202 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM202 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 24%) nucleotide sequence of GAM202 RNA is designated SEQ ID:2922, and is provided hereinbelow with reference to the sequence listing part.

[2818] GAM202 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM202 target RNA, herein designated GAM TARGET RNA. GAM202 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2819] GAM202 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM202 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM202 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM202 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM202 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2820] The complementary binding of GAM202 RNA, herein designated GAM RNA, to target binding sites on GAM202 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM202 target RNA, herein designated GAM TARGET RNA, into GAM202 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2821] It is appreciated that GAM202 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM202 target genes. The mRNA of each one of this plurality of GAM202 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM202 RNA, herein designated GAM RNA, and which when bound by GAM202 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM202 target proteins.

[2822] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM202 gene, herein designated GAM GENE, on one or more GAM202 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2823] It is yet further appreciated that specific functions, and accordingly utilities, of GAM202 correlate with, and may be deduced from, the identity of the target genes which GAM202 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2824] Nucleotide sequences of the GAM202 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM202 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM202 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM202 are further described hereinbelow with reference to Table Table1.

[2825] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM202 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2826]

[2827] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 203 (GAM203) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2828] GAM203 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM203 was detected is described hereinabove with reference to Figs. 2-8.

[2829] GAM203 gene, herein designated GAM GENE, and GAM203 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2830] GAM203 gene, herein designated GAM GENE, encodes a GAM203 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM203 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM203 precursor RNA is desig-

nated SEQ ID:2946, and is provided hereinbelow with reference to the sequence listing part.

[2831] GAM203 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM203 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2832] An enzyme complex designated DICER COMPLEX, dices the GAM203 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM203 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM203 RNA is designated SEQ ID:2947, and is provided hereinbelow with reference to the sequence listing part.

[2833] GAM203 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM203 target RNA, herein designated GAM TARGET RNA. GAM203 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2834] GAM203 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM203 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM203 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM203 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM203

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2835] The complementary binding of GAM203 RNA, herein designated GAM RNA, to target binding sites on GAM203 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM203 target RNA, herein designated GAM TARGET RNA, into GAM203 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2836] It is appreciated that GAM203 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM203 target genes. The mRNA of each one of this plurality of GAM203 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM203 RNA, herein designated GAM RNA, and which when bound by GAM203 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM203 target proteins.

[2837] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM203 gene, herein designated GAM GENE, on one or more GAM203 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2838] It is yet further appreciated that specific functions, and accordingly utilities, of GAM203 correlate with, and may be deduced from, the identity of the target genes which GAM203 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2839] Nucleotide sequences of the GAM203 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM203 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM203 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM203 are further described hereinbelow with reference to Table Table1.

[2840] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM203 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2841]

[2842] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 204 (GAM204) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2843] GAM204 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM204 was detected is described hereinabove with reference to Figs. 2-8.

[2844] GAM204 gene, herein designated GAM GENE, and

GAM204 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2845] GAM204 gene, herein designated GAM GENE, encodes a GAM204 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM204 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM204 precursor RNA is designated SEQ ID:2953, and is provided hereinbelow with reference to the sequence listing part.

[2846] GAM204 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM204 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2847] An enzyme complex designated DICER COMPLEX, dices the GAM204 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM204 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM204 RNA is designated SEQ ID:2954, and is provided hereinbelow with reference to the sequence listing part.

[2848] GAM204 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM204 target RNA, herein designated GAM TARGET RNA. GAM204 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2849] GAM204 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM204 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM204 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM204 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM204 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2850] The complementary binding of GAM204 RNA, herein designated GAM RNA, to target binding sites on GAM204 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM204 target RNA, herein designated GAM TARGET RNA, into GAM204 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2851] It is appreciated that GAM204 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM204 target genes. The mRNA of each one of this plurality of GAM204 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM204 RNA, herein designated GAM RNA, and which when bound by GAM204 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM204 target proteins.

[2852] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM204 gene, herein designated GAM GENE, on one or more GAM204 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2853] It is yet further appreciated that specific functions, and accordingly utilities, of GAM204 correlate with, and may be deduced from, the identity of the target genes which GAM204 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2854] Nucleotide sequences of the GAM204 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM204 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM204 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM204 are further described hereinbelow with reference to Table Table1.

[2855] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM204 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2856]

[2857] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 205 (GAM205) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2858] GAM205 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM205 was detected is described hereinabove with reference to Figs. 2-8.

[2859] GAM205 gene, herein designated GAM GENE, and GAM205 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2860] GAM205 gene, herein designated GAM GENE, encodes a GAM205 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM205 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM205 precursor RNA is designated SEQ ID:2967, and is provided hereinbelow with reference to the sequence listing part.

[2861] GAM205 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM205 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2862] An enzyme complex designated DICER COMPLEX, dices the GAM205 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM205 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 40%) nucleotide sequence of GAM205 RNA is designated SEQ ID:2968, and is provided hereinbelow with reference to the sequence listing part.

[2863] GAM205 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM205 target RNA, herein designated GAM TARGET RNA. GAM205 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2864] GAM205 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM205 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM205 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM205 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM205 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2865] The complementary binding of GAM205 RNA, herein designated GAM RNA, to target binding sites on GAM205 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM205 target RNA, herein designated GAM TARGET RNA, into GAM205 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2866] It is appreciated that GAM205 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM205 target genes. The mRNA of each one of this plurality of GAM205 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM205 RNA, herein designated GAM RNA, and which when bound by GAM205 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM205 target proteins.

[2867] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM205 gene, herein designated GAM GENE, on one or more GAM205 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2868] It is yet further appreciated that specific functions, and accordingly utilities, of GAM205 correlate with, and may be deduced from, the identity of the target genes which GAM205 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2869] Nucleotide sequences of the GAM205 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM205 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM205 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM205 are further described hereinbelow with reference to Table Table1.

[2870] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM205 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2871]

[2872] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 206 (GAM206) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2873] GAM206 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM206 was detected is described hereinabove with reference to Figs. 2-8.

[2874] GAM206 gene, herein designated GAM GENE, and GAM206 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2875] GAM206 gene, herein designated GAM GENE, encodes a GAM206 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM206 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM206 precursor RNA is designated SEQ ID:2973, and is provided hereinbelow with reference to the sequence listing part.

[2876] GAM206 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM206 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2877] An enzyme complex designated DICER COMPLEX, dices the GAM206 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM206 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 82%) nucleotide sequence of GAM206 RNA is designated SEQ ID:2974, and is provided hereinbelow with reference to the sequence listing part.

[2878] GAM206 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM206 target RNA, herein designated GAM TARGET RNA. GAM206 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2879] GAM206 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM206 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM206 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM206 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM206 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2880] The complementary binding of GAM206 RNA, herein designated GAM RNA, to target binding sites on GAM206 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM206 target RNA, herein designated GAM TARGET RNA, into GAM206 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2881] It is appreciated that GAM206 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM206 target genes. The mRNA of each one of this plurality of GAM206 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM206 RNA,

herein designated GAM RNA, and which when bound by GAM206 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM206 target proteins.

[2882] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM206 gene, herein designated GAM GENE, on one or more GAM206 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2883] It is yet further appreciated that specific functions, and accordingly utilities, of GAM206 correlate with, and may be deduced from, the identity of the target genes which

GAM206 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2884] Nucleotide sequences of the GAM206 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM206 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM206 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM206 are further described hereinbelow with reference to Table Table1.

[2885] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM206 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2886]

[2887] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 207 (GAM207) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2888] GAM207 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM207 was detected is described hereinabove with reference to Figs. 2-8.

[2889] GAM207 gene, herein designated GAM GENE, and GAM207 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2890] GAM207 gene, herein designated GAM GENE, encodes a GAM207 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM207 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM207 precursor RNA is designated SEQ ID:3004, and is provided hereinbelow with reference to the sequence listing part.

[2891] GAM207 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM207 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[2892] An enzyme complex designated DICER COMPLEX, dices the GAM207 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM207 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 26%) nucleotide sequence of GAM207 RNA is designated SEQ ID:3005, and is provided hereinbelow with reference to the sequence listing part.

[2893] GAM207 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM207 target RNA, herein designated GAM TARGET RNA.
GAM207 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2894] GAM207 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM207 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM207 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM207 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM207 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2895] The complementary binding of GAM207 RNA, herein designated GAM RNA, to target binding sites on GAM207 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM207 target RNA, herein desig-

nated GAM TARGET RNA, into GAM207 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2896] It is appreciated that GAM207 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM207 target genes. The mRNA of each one of this plurality of GAM207 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM207 RNA, herein designated GAM RNA, and which when bound by GAM207 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM207 target proteins.

[2897] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM207 gene, herein designated GAM GENE, on one or more GAM207 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2898] It is yet further appreciated that specific functions, and accordingly utilities, of GAM207 correlate with, and may be deduced from, the identity of the target genes which GAM207 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2899] Nucleotide sequences of the GAM207 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM207 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM207 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM207 are further described hereinbelow with reference to Table Table1.

[2900] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM207 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[2901]

[2902] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 208 (GAM208) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2903] GAM208 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM208 was detected is described hereinabove with reference to Figs. 2-8.

[2904] GAM208 gene, herein designated GAM GENE, and GAM208 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2905] GAM208 gene, herein designated GAM GENE, encodes a GAM208 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM208 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM208 precursor RNA is designated SEQ ID:3021, and is provided hereinbelow with ref-

erence to the sequence listing part.

[2906] GAM208 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM208 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2907] An enzyme complex designated DICER COMPLEX, dices the GAM208 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM208 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 79%) nucleotide sequence of GAM208 RNA is designated SEQ ID:3022, and is provided hereinbelow with reference to the sequence listing part.

[2908] GAM208 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM208 target RNA, herein designated GAM TARGET RNA.

GAM208 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2909] GAM208 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM208 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM208 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM208 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM208 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2910] The complementary binding of GAM208 RNA, herein designated GAM RNA, to target binding sites on GAM208 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM208 target RNA, herein designated GAM TARGET RNA, into GAM208 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2911] It is appreciated that GAM208 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM208 target genes. The mRNA of each one of this plurality of GAM208 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM208 RNA, herein designated GAM RNA, and which when bound by GAM208 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM208 target proteins.

[2912] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM208 gene, herein designated GAM GENE, on one or more GAM208 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2913] It is yet further appreciated that specific functions, and accordingly utilities, of GAM208 correlate with, and may be deduced from, the identity of the target genes which GAM208 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2914] Nucleotide sequences of the GAM208 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM208 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM208 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM208 are further described hereinbelow with reference to Table Table1.

[2915] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM208 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2916]

[2917] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 209 (GAM209) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2918] GAM209 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM209 was detected is described hereinabove with reference to Figs. 2-8.

[2919] GAM209 gene, herein designated GAM GENE, and GAM209 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[2920] GAM209 gene, herein designated GAM GENE, encodes a GAM209 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM209 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM209 precursor RNA is designated SEQ ID:3030, and is provided hereinbelow with reference to the sequence listing part.

[2921] GAM209 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM209 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2922] An enzyme complex designated DICER COMPLEX, dices the GAM209 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM209 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 40%) nucleotide sequence of GAM209 RNA is designated SEQ ID:3031, and is provided hereinbelow with reference to the sequence listing part.

[2923] GAM209 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM209 target RNA, herein designated GAM TARGET RNA. GAM209 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2924] GAM209 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM209 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM209 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM209 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM209 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2925] The complementary binding of GAM209 RNA, herein designated GAM RNA, to target binding sites on GAM209 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM209 target RNA, herein designated GAM TARGET RNA, into GAM209 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2926] It is appreciated that GAM209 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM209 target genes. The mRNA of each one of this plurality of GAM209 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM209 RNA, herein designated GAM RNA, and which when bound by GAM209 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM209 target proteins.

[2927] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM209 gene, herein designated GAM GENE, on one or more GAM209 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[2928] It is yet further appreciated that specific functions, and accordingly utilities, of GAM209 correlate with, and may be deduced from, the identity of the target genes which GAM209 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2929] Nucleotide sequences of the GAM209 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM209 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM209 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM209 are further described hereinbelow with reference to Table Table1.

[2930] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM209 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2931]

[2932] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

210 (GAM210) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2933] GAM210 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM210 was detected is described hereinabove with reference to Figs. 2-8.

[2934] GAM210 gene, herein designated GAM GENE, and GAM210 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2935] GAM210 gene, herein designated GAM GENE, encodes a GAM210 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM210 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM210 precursor RNA is designated SEQ ID:3043, and is provided hereinbelow with reference to the sequence listing part.

[2936] GAM210 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM210 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2937] An enzyme complex designated DICER COMPLEX, dices the GAM210 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM210 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM210 RNA is designated SEQ ID:3044, and is provided hereinbelow with reference to the sequence listing part.

[2938] GAM210 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM210 target RNA, herein designated GAM TARGET RNA. GAM210 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2939] GAM210 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM210 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM210 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM210 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM210 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2940] The complementary binding of GAM210 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM210 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM210 target RNA, herein designated GAM TARGET RNA, into GAM210 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2941] It is appreciated that GAM210 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM210 target genes. The mRNA of each one of this plurality of GAM210 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM210 RNA, herein designated GAM RNA, and which when bound by GAM210 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM210 target proteins.

[2942] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM210 gene, herein designated GAM GENE, on one or more GAM210 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2943] It is yet further appreciated that specific functions, and accordingly utilities, of GAM210 correlate with, and may be deduced from, the identity of the target genes which GAM210 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2944] Nucleotide sequences of the GAM210 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM210 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM210 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM210 are further described hereinbelow with reference to Table Table1.

[2945] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM210 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2946]

[2947] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 211 (GAM211) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2948] GAM211 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM211 was detected is described hereinabove with reference to Figs. 2-8.

[2949] GAM211 gene, herein designated GAM GENE, and GAM211 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2950] GAM211 gene, herein designated GAM GENE, encodes a GAM211 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM211 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM211 precursor RNA is designated SEQ ID:3049, and is provided hereinbelow with reference to the sequence listing part.

[2951] GAM211 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM211 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2952] An enzyme complex designated DICER COMPLEX, dices the GAM211 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM211 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 66%) nucleotide sequence of GAM211 RNA is designated SEQ ID:3050, and is provided hereinbelow with reference to the sequence listing part.

[2953] GAM211 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM211 target RNA, herein designated GAM TARGET RNA. GAM211 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2954] GAM211 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM211 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM211 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM211 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM211 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2955] The complementary binding of GAM211 RNA, herein designated GAM RNA, to target binding sites on GAM211 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM211 target RNA, herein designated GAM TARGET RNA, into GAM211 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2956] It is appreciated that GAM211 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM211 target genes. The mRNA of each one of this plurality of GAM211 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM211 RNA, herein designated GAM RNA, and which when bound by

GAM211 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM211 target proteins.

[2957] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM211 gene, herein designated GAM GENE, on one or more GAM211 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2958] It is yet further appreciated that specific functions, and accordingly utilities, of GAM211 correlate with, and may be deduced from, the identity of the target genes which GAM211 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[2959] Nucleotide sequences of the GAM211 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM211 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM211 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM211 are further described hereinbelow with reference to Table Table1.

[2960] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM211 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2961]

[2962] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 212 (GAM212) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2963] GAM212 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM212 was detected is described hereinabove with reference to Figs. 2-8.

[2964] GAM212 gene, herein designated GAM GENE, and GAM212 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2965] GAM212 gene, herein designated GAM GENE, encodes a GAM212 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM212 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM212 precursor RNA is designated SEQ ID:3069, and is provided hereinbelow with reference to the sequence listing part.

[2966] GAM212 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM212 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[2967] An enzyme complex designated DICER COMPLEX, dices the GAM212 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM212 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM212 RNA is designated SEQ ID:3070, and is provided hereinbelow with reference to the sequence listing part.

[2968] GAM212 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM212 target RNA, herein designated GAM TARGET RNA. GAM212 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2969] GAM212 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM212 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM212 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM212 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM212 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2970] The complementary binding of GAM212 RNA, herein designated GAM RNA, to target binding sites on GAM212 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM212 target RNA, herein designated GAM TARGET RNA, into GAM212 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2971] It is appreciated that GAM212 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM212 target genes. The mRNA of each one of this plurality of GAM212 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM212 RNA, herein designated GAM RNA, and which when bound by GAM212 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM212 target proteins.

[2972] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM212 gene, herein designated GAM GENE, on one or more GAM212 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2973] It is yet further appreciated that specific functions, and accordingly utilities, of GAM212 correlate with, and may be deduced from, the identity of the target genes which GAM212 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2974] Nucleotide sequences of the GAM212 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM212 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM212 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM212 are further described hereinbelow with reference to Table Table1.

[2975] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM212 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2976]

[2977] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 213 (GAM213) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2978] GAM213 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM213 was detected is described hereinabove with reference to Figs. 2-8.

[2979] GAM213 gene, herein designated GAM GENE, and GAM213 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2980] GAM213 gene, herein designated GAM GENE, encodes a GAM213 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM213 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM213 precursor RNA is designated SEQ ID:3075, and is provided hereinbelow with reference to the sequence listing part.

[2981] GAM213 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM213 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2982] An enzyme complex designated DICER COMPLEX, dices the GAM213 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM213 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM213 RNA is designated SEQ ID:3076, and is provided hereinbelow with reference to the sequence listing part.

[2983] GAM213 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM213

target RNA, herein designated GAM TARGET RNA.

GAM213 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2984] GAM213 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM213 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM213 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM213 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM213 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[2985] The complementary binding of GAM213 RNA, herein designated GAM RNA, to target binding sites on GAM213 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM213 target RNA, herein designated GAM TARGET RNA, into GAM213 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[2986] It is appreciated that GAM213 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM213 target genes. The mRNA of each one of this plurality of GAM213 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM213 RNA, herein designated GAM RNA, and which when bound by GAM213 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM213 target proteins.

[2987] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM213 gene, herein designated GAM GENE, on one or more GAM213 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[2988] It is yet further appreciated that specific functions, and accordingly utilities, of GAM213 correlate with, and may be deduced from, the identity of the target genes which GAM213 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[2989] Nucleotide sequences of the GAM213 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM213 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM213 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM213 are further described hereinbelow with reference to Table Table1.

[2990] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM213 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[2991]

[2992] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 214 (GAM214) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[2993] GAM214 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM214 was detected is described hereinabove with reference to Figs. 2-8.

[2994] GAM214 gene, herein designated GAM GENE, and GAM214 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[2995] GAM214 gene, herein designated GAM GENE, encodes a GAM214 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM214 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM214 precursor RNA is designated SEQ ID:3081, and is provided hereinbelow with reference to the sequence listing part.

[2996] GAM214 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM214 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[2997] An enzyme complex designated DICER COMPLEX, dices the GAM214 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM214 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM214 RNA is designated SEQ ID:3082, and is provided hereinbelow with reference to the sequence listing part.

[2998] GAM214 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM214 target RNA, herein designated GAM TARGET RNA. GAM214 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[2999] GAM214 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM214 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM214 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM214 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM214 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3000] The complementary binding of GAM214 RNA, herein designated GAM RNA, to target binding sites on GAM214 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM214 target RNA, herein designated GAM TARGET RNA, into GAM214 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3001] It is appreciated that GAM214 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM214 target genes. The mRNA of each one of this plu-

rality of GAM214 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM214 RNA, herein designated GAM RNA, and which when bound by GAM214 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM214 target proteins.

[3002] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM214 gene, herein designated GAM GENE, on one or more GAM214 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3003] It is yet further appreciated that specific functions, and accordingly utilities, of GAM214 correlate with, and may be deduced from, the identity of the target genes which GAM214 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3004] Nucleotide sequences of the GAM214 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM214 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM214 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM214 are further described hereinbelow with reference to Table Table1.

[3005] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM214 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3006]

[3007] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 215 (GAM215) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[3008] GAM215 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM215 was detected is described hereinabove with reference to Figs. 2-8.

[3009] GAM215 gene, herein designated GAM GENE, and GAM215 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3010] GAM215 gene, herein designated GAM GENE, encodes a GAM215 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM215 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM215 precursor RNA is designated SEQ ID:3101, and is provided hereinbelow with reference to the sequence listing part.

[3011] GAM215 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM215 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3012] An enzyme complex designated DICER COMPLEX, dices the GAM215 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM215 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM215 RNA is designated SEQ ID:3102, and is provided hereinbelow with reference to the sequence listing part.

[3013] GAM215 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM215 target RNA, herein designated GAM TARGET RNA.
GAM215 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[3014] GAM215 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM215 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM215 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM215 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM215 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3015] The complementary binding of GAM215 RNA, herein designated GAM RNA, to target binding sites on GAM215 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM215 target RNA, herein designated GAM TARGET RNA, into GAM215 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3016] It is appreciated that GAM215 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM215 target genes. The mRNA of each one of this plurality of GAM215 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM215 RNA, herein designated GAM RNA, and which when bound by GAM215 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM215 target proteins.

[3017] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM215 gene, herein designated GAM GENE, on one or more GAM215 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3018] It is yet further appreciated that specific functions, and accordingly utilities, of GAM215 correlate with, and may be deduced from, the identity of the target genes which GAM215 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3019] Nucleotide sequences of the GAM215 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM215 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM215 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM215 are further described hereinbelow with reference to Table Table1.

[3020] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM215 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3021]

[3022] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 216 (GAM216) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3023] GAM216 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM216 was detected is described hereinabove with reference to Figs. 2-8.

[3024] GAM216 gene, herein designated GAM GENE, and GAM216 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3025] GAM216 gene, herein designated GAM GENE, encodes a GAM216 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM216 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM216 precursor RNA is designated SEQ ID:3118, and is provided hereinbelow with reference to the sequence listing part.

[3026] GAM216 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM216 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3027] An enzyme complex designated DICER COMPLEX, dices the GAM216 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM216 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 32%) nucleotide sequence of

GAM216 RNA is designated SEQ ID:3119, and is provided hereinbelow with reference to the sequence listing part.

[3028] GAM216 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM216 target RNA, herein designated GAM TARGET RNA. GAM216 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3029] GAM216 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM216 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM216 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM216 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM216 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3030] The complementary binding of GAM216 RNA, herein designated GAM RNA, to target binding sites on GAM216 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM216 target RNA, herein designated GAM TARGET RNA, into GAM216 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3031] It is appreciated that GAM216 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM216 target genes. The mRNA of each one of this plurality of GAM216 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM216 RNA, herein designated GAM RNA, and which when bound by GAM216 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM216 target proteins.

[3032] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM216 gene, herein designated GAM GENE, on one or more GAM216 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3033] It is yet further appreciated that specific functions, and accordingly utilities, of GAM216 correlate with, and may be deduced from, the identity of the target genes which GAM216 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3034] Nucleotide sequences of the GAM216 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM216 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM216 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM216 are further described hereinbelow with reference to Table Table1.

[3035] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM216 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3036]

[3037] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 217 (GAM217) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3038] GAM217 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM217 was detected is described hereinabove

with reference to Figs. 2-8.

[3039] GAM217 gene, herein designated GAM GENE, and GAM217 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3040] GAM217 gene, herein designated GAM GENE, encodes a GAM217 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM217 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM217 precursor RNA is designated SEQ ID:3132, and is provided hereinbelow with reference to the sequence listing part.

[3041] GAM217 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM217 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3042] An enzyme complex designated DICER COMPLEX, dices the GAM217 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM217 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM217 RNA is designated SEQ ID:3133, and is provided hereinbelow with reference to the sequence listing part.

[3043] GAM217 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM217 target RNA, herein designated GAM TARGET RNA. GAM217 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3044] GAM217 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM217 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM217 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM217 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM217 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3045] The complementary binding of GAM217 RNA, herein designated GAM RNA, to target binding sites on GAM217 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM217 target RNA, herein designated GAM TARGET RNA, into GAM217 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[3046] It is appreciated that GAM217 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM217 target genes. The mRNA of each one of this plurality of GAM217 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM217 RNA, herein designated GAM RNA, and which when bound by GAM217 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM217 target proteins.

[3047] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM217 gene, herein designated GAM GENE, on one or more GAM217 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3048] It is yet further appreciated that specific functions, and accordingly utilities, of GAM217 correlate with, and may be deduced from, the identity of the target genes which GAM217 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3049] Nucleotide sequences of the GAM217 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM217 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM217 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM217 are further described hereinbelow with reference to Table Table1.

[3050] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM217 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3051]

[3052] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 218 (GAM218) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3053] GAM218 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM218 was detected is described hereinabove with reference to Figs. 2-8.

[3054] GAM218 gene, herein designated GAM GENE, and GAM218 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3055] GAM218 gene, herein designated GAM GENE, encodes a GAM218 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM218 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM218 precursor RNA is designated SEQ ID:3172, and is provided hereinbelow with reference to the sequence listing part.

[3056] GAM218 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM218 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3057] An enzyme complex designated DICER COMPLEX, dices the GAM218 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM218 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM218 RNA is designated SEQ ID:3173, and is provided hereinbelow with reference to the sequence listing part.

[3058] GAM218 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM218 target RNA, herein designated GAM TARGET RNA.

GAM218 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3059] GAM218 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM218 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM218 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM218 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM218 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3060] The complementary binding of GAM218 RNA, herein designated GAM RNA, to target binding sites on GAM218 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM218 target RNA, herein designated GAM TARGET RNA, into GAM218 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3061] It is appreciated that GAM218 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM218 target genes. The mRNA of each one of this plurality of GAM218 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM218 RNA, herein designated GAM RNA, and which when bound by GAM218 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM218 target proteins.

[3062] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM218 gene, herein designated GAM GENE, on one or more GAM218 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3063] It is yet further appreciated that specific functions, and accordingly utilities, of GAM218 correlate with, and may be deduced from, the identity of the target genes which GAM218 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3064] Nucleotide sequences of the GAM218 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM218 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM218 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM218 are further described hereinbelow with reference to Table Table1.

[3065] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM218 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3066]

[3067] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 219 (GAM219) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3068] GAM219 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM219 was detected is described hereinabove with reference to Figs. 2-8.

[3069] GAM219 gene, herein designated GAM GENE, and GAM219 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3070] GAM219 gene, herein designated GAM GENE, encodes a

GAM219 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM219 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM219 precursor RNA is designated SEQ ID:3204, and is provided hereinbelow with reference to the sequence listing part.

[3071] GAM219 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM219 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3072] An enzyme complex designated DICER COMPLEX, dices the GAM219 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM219 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM219 RNA is designated SEQ ID:3205, and is provided hereinbelow with reference to the sequence listing part.

[3073] GAM219 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM219 target RNA, herein designated GAM TARGET RNA. GAM219 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3074] GAM219 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM219 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM219 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM219 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM219

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3075] The complementary binding of GAM219 RNA, herein designated GAM RNA, to target binding sites on GAM219 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM219 target RNA, herein designated GAM TARGET RNA, into GAM219 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3076] It is appreciated that GAM219 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM219 target genes. The mRNA of each one of this plurality of GAM219 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM219 RNA, herein designated GAM RNA, and which when bound by GAM219 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM219 target proteins.

[3077] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM219 gene, herein designated GAM GENE, on one or more GAM219 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3078] It is yet further appreciated that specific functions, and accordingly utilities, of GAM219 correlate with, and may be deduced from, the identity of the target genes which GAM219 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3079] Nucleotide sequences of the GAM219 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM219 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM219 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM219 are further described hereinbelow with reference to Table Table1.

[3080] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM219 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3081]

[3082] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 220 (GAM220) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3083] GAM220 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM220 was detected is described hereinabove with reference to Figs. 2-8.

[3084] GAM220 gene, herein designated GAM GENE, and

GAM220 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3085] GAM220 gene, herein designated GAM GENE, encodes a GAM220 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM220 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM220 precursor RNA is designated SEQ ID:3210, and is provided hereinbelow with reference to the sequence listing part.

[3086] GAM220 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM220 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3087] An enzyme complex designated DICER COMPLEX, dices the GAM220 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM220 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM220 RNA is designated SEQ ID:3211, and is provided hereinbelow with reference to the sequence listing part.

[3088] GAM220 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM220 target RNA, herein designated GAM TARGET RNA. GAM220 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3089] GAM220 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM220 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM220 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM220 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM220 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3090] The complementary binding of GAM220 RNA, herein designated GAM RNA, to target binding sites on GAM220 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM220 target RNA, herein designated GAM TARGET RNA, into GAM220 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3091] It is appreciated that GAM220 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM220 target genes. The mRNA of each one of this plurality of GAM220 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM220 RNA, herein designated GAM RNA, and which when bound by GAM220 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM220 target proteins.

[3092] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM220 gene, herein designated GAM GENE, on one or more GAM220 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3093] It is yet further appreciated that specific functions, and accordingly utilities, of GAM220 correlate with, and may be deduced from, the identity of the target genes which GAM220 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3094] Nucleotide sequences of the GAM220 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM220 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM220 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM220 are further described hereinbelow with reference to Table Table1.

[3095] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM220 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3096]

[3097] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 221 (GAM221) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3098] GAM221 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM221 was detected is described hereinabove with reference to Figs. 2-8.

[3099] GAM221 gene, herein designated GAM GENE, and GAM221 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3100] GAM221 gene, herein designated GAM GENE, encodes a GAM221 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM221 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM221 precursor RNA is designated SEQ ID:3247, and is provided hereinbelow with reference to the sequence listing part.

[3101] GAM221 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM221 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3102] An enzyme complex designated DICER COMPLEX, dices the GAM221 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM221 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 33%) nucleotide sequence of GAM221 RNA is designated SEQ ID:3248, and is provided hereinbelow with reference to the sequence listing part.

[3103] GAM221 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM221 target RNA, herein designated GAM TARGET RNA. GAM221 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3104] GAM221 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM221 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM221 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM221 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM221 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3105] The complementary binding of GAM221 RNA, herein designated GAM RNA, to target binding sites on GAM221 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM221 target RNA, herein designated GAM TARGET RNA, into GAM221 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3106] It is appreciated that GAM221 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM221 target genes. The mRNA of each one of this plurality of GAM221 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM221 RNA, herein designated GAM RNA, and which when bound by GAM221 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM221 target proteins.

[3107] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM221 gene, herein designated GAM GENE, on one or more GAM221 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3108] It is yet further appreciated that specific functions, and accordingly utilities, of GAM221 correlate with, and may be deduced from, the identity of the target genes which GAM221 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3109] Nucleotide sequences of the GAM221 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM221 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM221 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM221 are further described hereinbelow with reference to Table Table1.

[3110] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM221 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3111]

[3112] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 222 (GAM222) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3113] GAM222 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM222 was detected is described hereinabove with reference to Figs. 2-8.

[3114] GAM222 gene, herein designated GAM GENE, and GAM222 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3115] GAM222 gene, herein designated GAM GENE, encodes a GAM222 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM222 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM222 precursor RNA is designated SEQ ID:3266, and is provided hereinbelow with reference to the sequence listing part.

[3116] GAM222 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM222 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3117] An enzyme complex designated DICER COMPLEX, dices the GAM222 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM222 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 36%) nucleotide sequence of GAM222 RNA is designated SEQ ID:3267, and is provided hereinbelow with reference to the sequence listing part.

[3118] GAM222 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM222 target RNA, herein designated GAM TARGET RNA. GAM222 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3119] GAM222 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM222 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM222 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM222 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM222 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3120] The complementary binding of GAM222 RNA, herein designated GAM RNA, to target binding sites on GAM222 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM222 target RNA, herein designated GAM TARGET RNA, into GAM222 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3121] It is appreciated that GAM222 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM222 target genes. The mRNA of each one of this plurality of GAM222 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM222 RNA,

herein designated GAM RNA, and which when bound by GAM222 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM222 target proteins.

[3122] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM222 gene, herein designated GAM GENE, on one or more GAM222 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3123] It is yet further appreciated that specific functions, and accordingly utilities, of GAM222 correlate with, and may be deduced from, the identity of the target genes which

GAM222 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3124] Nucleotide sequences of the GAM222 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM222 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM222 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM222 are further described hereinbelow with reference to Table Table1.

[3125] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM222 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3126]

[3127] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 223 (GAM223) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3128] GAM223 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM223 was detected is described hereinabove with reference to Figs. 2-8.

[3129] GAM223 gene, herein designated GAM GENE, and GAM223 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3130] GAM223 gene, herein designated GAM GENE, encodes a GAM223 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM223 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM223 precursor RNA is designated SEQ ID:3279, and is provided hereinbelow with reference to the sequence listing part.

[3131] GAM223 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM223 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[3132] An enzyme complex designated DICER COMPLEX, dices the GAM223 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM223 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 25%) nucleotide sequence of GAM223 RNA is designated SEQ ID:3280, and is provided hereinbelow with reference to the sequence listing part.

[3133] GAM223 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM223 target RNA, herein designated GAM TARGET RNA.
GAM223 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3134] GAM223 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM223 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM223 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM223 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM223 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3135] The complementary binding of GAM223 RNA, herein designated GAM RNA, to target binding sites on GAM223 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM223 target RNA, herein desig-

nated GAM TARGET RNA, into GAM223 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3136] It is appreciated that GAM223 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM223 target genes. The mRNA of each one of this plurality of GAM223 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM223 RNA, herein designated GAM RNA, and which when bound by GAM223 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM223 target proteins.

[3137] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM223 gene, herein designated GAM GENE, on one or more GAM223 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3138] It is yet further appreciated that specific functions, and accordingly utilities, of GAM223 correlate with, and may be deduced from, the identity of the target genes which GAM223 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3139] Nucleotide sequences of the GAM223 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM223 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM223 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM223 are further described hereinbelow with reference to Table Table1.

[3140] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM223 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[3141]

[3142] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 224 (GAM224) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3143] GAM224 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM224 was detected is described hereinabove with reference to Figs. 2-8.

[3144] GAM224 gene, herein designated GAM GENE, and GAM224 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3145] GAM224 gene, herein designated GAM GENE, encodes a GAM224 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM224 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM224 precursor RNA is designated SEQ ID:3287, and is provided hereinbelow with ref-

erence to the sequence listing part.

[3146] GAM224 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM224 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3147] An enzyme complex designated DICER COMPLEX, dices the GAM224 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM224 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM224 RNA is designated SEQ ID:3288, and is provided hereinbelow with reference to the sequence listing part.

[3148] GAM224 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM224 target RNA, herein designated GAM TARGET RNA.

GAM224 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3149] GAM224 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM224 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM224 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM224 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM224 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3150] The complementary binding of GAM224 RNA, herein designated GAM RNA, to target binding sites on GAM224 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM224 target RNA, herein designated GAM TARGET RNA, into GAM224 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3151] It is appreciated that GAM224 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM224 target genes. The mRNA of each one of this plurality of GAM224 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM224 RNA, herein designated GAM RNA, and which when bound by GAM224 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM224 target proteins.

[3152] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM224 gene, herein designated GAM GENE, on one or more GAM224 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3153] It is yet further appreciated that specific functions, and accordingly utilities, of GAM224 correlate with, and may be deduced from, the identity of the target genes which GAM224 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3154] Nucleotide sequences of the GAM224 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM224 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM224 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM224 are further described hereinbelow with reference to Table Table1.

[3155] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM224 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3156]

[3157] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 225 (GAM225) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3158] GAM225 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM225 was detected is described hereinabove with reference to Figs. 2-8.

[3159] GAM225 gene, herein designated GAM GENE, and GAM225 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[3160] GAM225 gene, herein designated GAM GENE, encodes a GAM225 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM225 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM225 precursor RNA is designated SEQ ID:3306, and is provided hereinbelow with reference to the sequence listing part.

[3161] GAM225 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM225 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3162] An enzyme complex designated DICER COMPLEX, dices the GAM225 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM225 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM225 RNA is designated SEQ ID:3307, and is provided hereinbelow with reference to the sequence listing part.

[3163] GAM225 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM225 target RNA, herein designated GAM TARGET RNA. GAM225 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3164] GAM225 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM225 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM225 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM225 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM225 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3165] The complementary binding of GAM225 RNA, herein designated GAM RNA, to target binding sites on GAM225 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM225 target RNA, herein designated GAM TARGET RNA, into GAM225 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3166] It is appreciated that GAM225 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM225 target genes. The mRNA of each one of this plurality of GAM225 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM225 RNA, herein designated GAM RNA, and which when bound by GAM225 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM225 target proteins.

[3167] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM225 gene, herein designated GAM GENE, on one or more GAM225 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[3168] It is yet further appreciated that specific functions, and accordingly utilities, of GAM225 correlate with, and may be deduced from, the identity of the target genes which GAM225 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3169] Nucleotide sequences of the GAM225 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM225 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM225 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM225 are further described hereinbelow with reference to Table Table1.

[3170] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM225 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3171]

[3172] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

226 (GAM226) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3173] GAM226 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM226 was detected is described hereinabove with reference to Figs. 2-8.

[3174] GAM226 gene, herein designated GAM GENE, and GAM226 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3175] GAM226 gene, herein designated GAM GENE, encodes a GAM226 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM226 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM226 precursor RNA is designated SEQ ID:3315, and is provided hereinbelow with reference to the sequence listing part.

[3176] GAM226 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM226 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3177] An enzyme complex designated DICER COMPLEX, dices the GAM226 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM226 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM226 RNA is designated SEQ ID:3316, and is provided hereinbelow with reference to the sequence listing part.

[3178] GAM226 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM226 target RNA, herein designated GAM TARGET RNA. GAM226 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3179] GAM226 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM226 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM226 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM226 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM226 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3180] The complementary binding of GAM226 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM226 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM226 target RNA, herein designated GAM TARGET RNA, into GAM226 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3181] It is appreciated that GAM226 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM226 target genes. The mRNA of each one of this plurality of GAM226 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM226 RNA, herein designated GAM RNA, and which when bound by GAM226 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM226 target proteins.

[3182] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM226 gene, herein designated GAM GENE, on one or more GAM226 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3183] It is yet further appreciated that specific functions, and accordingly utilities, of GAM226 correlate with, and may be deduced from, the identity of the target genes which GAM226 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3184] Nucleotide sequences of the GAM226 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM226 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM226 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM226 are further described hereinbelow with reference to Table Table1.

[3185] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM226 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3186]

[3187] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 227 (GAM227) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3188] GAM227 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM227 was detected is described hereinabove with reference to Figs. 2-8.

[3189] GAM227 gene, herein designated GAM GENE, and GAM227 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3190] GAM227 gene, herein designated GAM GENE, encodes a GAM227 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM227 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM227 precursor RNA is designated SEQ ID:3343, and is provided hereinbelow with reference to the sequence listing part.

[3191] GAM227 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM227 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3192] An enzyme complex designated DICER COMPLEX, dices the GAM227 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM227 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 56%) nucleotide sequence of GAM227 RNA is designated SEQ ID:3344, and is provided hereinbelow with reference to the sequence listing part.

[3193] GAM227 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM227 target RNA, herein designated GAM TARGET RNA. GAM227 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3194] GAM227 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM227 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM227 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM227 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM227 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3195] The complementary binding of GAM227 RNA, herein designated GAM RNA, to target binding sites on GAM227 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM227 target RNA, herein designated GAM TARGET RNA, into GAM227 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3196] It is appreciated that GAM227 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM227 target genes. The mRNA of each one of this plurality of GAM227 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM227 RNA, herein designated GAM RNA, and which when bound by

GAM227 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM227 target proteins.

[3197] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM227 gene, herein designated GAM GENE, on one or more GAM227 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3198] It is yet further appreciated that specific functions, and accordingly utilities, of GAM227 correlate with, and may be deduced from, the identity of the target genes which GAM227 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[3199] Nucleotide sequences of the GAM227 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM227 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM227 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM227 are further described hereinbelow with reference to Table Table1.

[3200] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM227 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3201]

[3202] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 228 (GAM228) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3203] GAM228 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM228 was detected is described hereinabove with reference to Figs. 2-8.

[3204] GAM228 gene, herein designated GAM GENE, and GAM228 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3205] GAM228 gene, herein designated GAM GENE, encodes a GAM228 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM228 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM228 precursor RNA is designated SEQ ID:3350, and is provided hereinbelow with reference to the sequence listing part.

[3206] GAM228 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM228 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[3207] An enzyme complex designated DICER COMPLEX, dices the GAM228 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM228 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM228 RNA is designated SEQ ID:3351, and is provided hereinbelow with reference to the sequence listing part.

[3208] GAM228 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM228 target RNA, herein designated GAM TARGET RNA. GAM228 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3209] GAM228 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM228 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM228 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM228 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM228 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3210] The complementary binding of GAM228 RNA, herein designated GAM RNA, to target binding sites on GAM228 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM228 target RNA, herein designated GAM TARGET RNA, into GAM228 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3211] It is appreciated that GAM228 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM228 target genes. The mRNA of each one of this plurality of GAM228 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM228 RNA, herein designated GAM RNA, and which when bound by GAM228 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM228 target proteins.

[3212] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM228 gene, herein designated GAM GENE, on one or more GAM228 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3213] It is yet further appreciated that specific functions, and accordingly utilities, of GAM228 correlate with, and may be deduced from, the identity of the target genes which GAM228 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3214] Nucleotide sequences of the GAM228 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM228 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM228 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM228 are further described hereinbelow with reference to Table Table1.

[3215] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM228 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3216]

[3217] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 229 (GAM229) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3218] GAM229 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM229 was detected is described hereinabove with reference to Figs. 2-8.

[3219] GAM229 gene, herein designated GAM GENE, and GAM229 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3220] GAM229 gene, herein designated GAM GENE, encodes a GAM229 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM229 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM229 precursor RNA is designated SEQ ID:3375, and is provided hereinbelow with reference to the sequence listing part.

[3221] GAM229 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM229 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3222] An enzyme complex designated DICER COMPLEX, dices the GAM229 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM229 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM229 RNA is designated SEQ ID:3376, and is provided hereinbelow with reference to the sequence listing part.

[3223] GAM229 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM229

target RNA, herein designated GAM TARGET RNA.

GAM229 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3224] GAM229 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM229 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM229 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM229 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM229 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3225] The complementary binding of GAM229 RNA, herein designated GAM RNA, to target binding sites on GAM229 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM229 target RNA, herein designated GAM TARGET RNA, into GAM229 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3226] It is appreciated that GAM229 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM229 target genes. The mRNA of each one of this plurality of GAM229 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM229 RNA, herein designated GAM RNA, and which when bound by GAM229 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM229 target proteins.

[3227] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM229 gene, herein designated GAM GENE, on one or more GAM229 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3228] It is yet further appreciated that specific functions, and accordingly utilities, of GAM229 correlate with, and may be deduced from, the identity of the target genes which GAM229 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3229] Nucleotide sequences of the GAM229 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM229 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM229 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM229 are further described hereinbelow with reference to Table Table1.

[3230] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM229 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3231]

[3232] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 230 (GAM230) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3233] GAM230 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM230 was detected is described hereinabove with reference to Figs. 2-8.

[3234] GAM230 gene, herein designated GAM GENE, and GAM230 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3235] GAM230 gene, herein designated GAM GENE, encodes a GAM230 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM230 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM230 precursor RNA is designated SEQ ID:3409, and is provided hereinbelow with reference to the sequence listing part.

[3236] GAM230 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM230 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3237] An enzyme complex designated DICER COMPLEX, dices the GAM230 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM230 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 93%) nucleotide sequence of GAM230 RNA is designated SEQ ID:3410, and is provided hereinbelow with reference to the sequence listing part.

[3238] GAM230 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM230 target RNA, herein designated GAM TARGET RNA. GAM230 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3239] GAM230 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM230 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM230 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM230 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM230 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3240] The complementary binding of GAM230 RNA, herein designated GAM RNA, to target binding sites on GAM230 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM230 target RNA, herein designated GAM TARGET RNA, into GAM230 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3241] It is appreciated that GAM230 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM230 target genes. The mRNA of each one of this plu-

rality of GAM230 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM230 RNA, herein designated GAM RNA, and which when bound by GAM230 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM230 target proteins.

[3242] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM230 gene, herein designated GAM GENE, on one or more GAM230 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3243] It is yet further appreciated that specific functions, and accordingly utilities, of GAM230 correlate with, and may be deduced from, the identity of the target genes which GAM230 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3244] Nucleotide sequences of the GAM230 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM230 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM230 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM230 are further described hereinbelow with reference to Table Table1.

[3245] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM230 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3246]

[3247] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 231 (GAM231) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[3248] GAM231 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM231 was detected is described hereinabove with reference to Figs. 2-8.

[3249] GAM231 gene, herein designated GAM GENE, and GAM231 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3250] GAM231 gene, herein designated GAM GENE, encodes a GAM231 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM231 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM231 precursor RNA is designated SEQ ID:3419, and is provided hereinbelow with reference to the sequence listing part.

[3251] GAM231 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM231 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3252] An enzyme complex designated DICER COMPLEX, dices the GAM231 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM231 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM231 RNA is designated SEQ ID:3420, and is provided hereinbelow with reference to the sequence listing part.

[3253] GAM231 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM231 target RNA, herein designated GAM TARGET RNA.
GAM231 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[3254] GAM231 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM231 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM231 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM231 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM231 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3255] The complementary binding of GAM231 RNA, herein designated GAM RNA, to target binding sites on GAM231 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM231 target RNA, herein designated GAM TARGET RNA, into GAM231 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3256] It is appreciated that GAM231 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM231 target genes. The mRNA of each one of this plurality of GAM231 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM231 RNA, herein designated GAM RNA, and which when bound by GAM231 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM231 target proteins.

[3257] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM231 gene, herein designated GAM GENE, on one or more GAM231 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3258] It is yet further appreciated that specific functions, and accordingly utilities, of GAM231 correlate with, and may be deduced from, the identity of the target genes which GAM231 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3259] Nucleotide sequences of the GAM231 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM231 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM231 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM231 are further described hereinbelow with reference to Table Table1.

[3260] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM231 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3261]

[3262] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 232 (GAM232) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3263] GAM232 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM232 was detected is described hereinabove with reference to Figs. 2-8.

[3264] GAM232 gene, herein designated GAM GENE, and GAM232 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3265] GAM232 gene, herein designated GAM GENE, encodes a GAM232 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM232 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM232 precursor RNA is designated SEQ ID:3431, and is provided hereinbelow with reference to the sequence listing part.

[3266] GAM232 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM232 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3267] An enzyme complex designated DICER COMPLEX, dices the GAM232 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM232 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of

GAM232 RNA is designated SEQ ID:3432, and is provided hereinbelow with reference to the sequence listing part.

[3268] GAM232 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM232 target RNA, herein designated GAM TARGET RNA. GAM232 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3269] GAM232 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM232 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM232 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM232 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM232 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3270] The complementary binding of GAM232 RNA, herein designated GAM RNA, to target binding sites on GAM232 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM232 target RNA, herein designated GAM TARGET RNA, into GAM232 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3271] It is appreciated that GAM232 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM232 target genes. The mRNA of each one of this plurality of GAM232 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM232 RNA, herein designated GAM RNA, and which when bound by GAM232 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM232 target proteins.

[3272] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM232 gene, herein designated GAM GENE, on one or more GAM232 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3273] It is yet further appreciated that specific functions, and accordingly utilities, of GAM232 correlate with, and may be deduced from, the identity of the target genes which GAM232 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3274] Nucleotide sequences of the GAM232 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM232 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM232 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM232 are further described hereinbelow with reference to Table Table1.

[3275] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM232 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3276]

[3277] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 233 (GAM233) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3278] GAM233 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM233 was detected is described hereinabove

with reference to Figs. 2-8.

[3279] GAM233 gene, herein designated GAM GENE, and GAM233 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3280] GAM233 gene, herein designated GAM GENE, encodes a GAM233 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM233 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM233 precursor RNA is designated SEQ ID:3449, and is provided hereinbelow with reference to the sequence listing part.

[3281] GAM233 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM233 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3282] An enzyme complex designated DICER COMPLEX, dices the GAM233 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM233 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 81%) nucleotide sequence of GAM233 RNA is designated SEQ ID:3450, and is provided hereinbelow with reference to the sequence listing part.

[3283] GAM233 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM233 target RNA, herein designated GAM TARGET RNA. GAM233 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3284] GAM233 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM233 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM233 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM233 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM233 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3285] The complementary binding of GAM233 RNA, herein designated GAM RNA, to target binding sites on GAM233 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM233 target RNA, herein designated GAM TARGET RNA, into GAM233 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[3286] It is appreciated that GAM233 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM233 target genes. The mRNA of each one of this plurality of GAM233 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM233 RNA, herein designated GAM RNA, and which when bound by GAM233 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM233 target proteins.

[3287] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM233 gene, herein designated GAM GENE, on one or more GAM233 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3288] It is yet further appreciated that specific functions, and accordingly utilities, of GAM233 correlate with, and may be deduced from, the identity of the target genes which GAM233 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3289] Nucleotide sequences of the GAM233 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM233 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM233 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM233 are further described hereinbelow with reference to Table Table1.

[3290] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM233 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3291]

[3292] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 234 (GAM234) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3293] GAM234 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM234 was detected is described hereinabove with reference to Figs. 2-8.

[3294] GAM234 gene, herein designated GAM GENE, and GAM234 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3295] GAM234 gene, herein designated GAM GENE, encodes a GAM234 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM234 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM234 precursor RNA is designated SEQ ID:3465, and is provided hereinbelow with reference to the sequence listing part.

[3296] GAM234 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM234 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3297] An enzyme complex designated DICER COMPLEX, dices the GAM234 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM234 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 44%) nucleotide sequence of GAM234 RNA is designated SEQ ID:3466, and is provided hereinbelow with reference to the sequence listing part.

[3298] GAM234 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM234 target RNA, herein designated GAM TARGET RNA.

GAM234 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3299] GAM234 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM234 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM234 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM234 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM234 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3300] The complementary binding of GAM234 RNA, herein designated GAM RNA, to target binding sites on GAM234 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM234 target RNA, herein designated GAM TARGET RNA, into GAM234 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3301] It is appreciated that GAM234 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM234 target genes. The mRNA of each one of this plurality of GAM234 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM234 RNA, herein designated GAM RNA, and which when bound by GAM234 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM234 target proteins.

[3302] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM234 gene, herein designated GAM GENE, on one or more GAM234 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3303] It is yet further appreciated that specific functions, and accordingly utilities, of GAM234 correlate with, and may be deduced from, the identity of the target genes which GAM234 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3304] Nucleotide sequences of the GAM234 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM234 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM234 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM234 are further described hereinbelow with reference to Table Table1.

[3305] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM234 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3306]

[3307] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 235 (GAM235) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3308] GAM235 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM235 was detected is described hereinabove with reference to Figs. 2-8.

[3309] GAM235 gene, herein designated GAM GENE, and GAM235 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3310] GAM235 gene, herein designated GAM GENE, encodes a

GAM235 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM235 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM235 precursor RNA is designated SEQ ID:3469, and is provided hereinbelow with reference to the sequence listing part.

[3311] GAM235 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM235 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3312] An enzyme complex designated DICER COMPLEX, dices the GAM235 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM235 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM235 RNA is designated SEQ ID:3470, and is provided hereinbelow with reference to the sequence listing part.

[3313] GAM235 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM235 target RNA, herein designated GAM TARGET RNA. GAM235 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3314] GAM235 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM235 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM235 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM235 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM235 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3315] The complementary binding of GAM235 RNA, herein designated GAM RNA, to target binding sites on GAM235 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM235 target RNA, herein designated GAM TARGET RNA, into GAM235 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3316] It is appreciated that GAM235 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM235 target genes. The mRNA of each one of this plurality of GAM235 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM235 RNA, herein designated GAM RNA, and which when bound by GAM235 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM235 target proteins.

[3317] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM235 gene, herein designated GAM GENE, on one or more GAM235 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3318] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM235 correlate with, and may be deduced from, the identity of the target genes which GAM235 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3319] Nucleotide sequences of the GAM235 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM235 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM235 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM235 are further described hereinbelow with reference to Table Table1.

[3320] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM235 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3321]

[3322] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 236 (GAM236) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[3323] GAM236 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM236 was detected is described hereinabove with reference to Figs. 2-8.

[3324] GAM236 gene, herein designated GAM GENE, and GAM236 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3325] GAM236 gene, herein designated GAM GENE, encodes a GAM236 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM236 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM236 precursor RNA is designated SEQ ID:3494, and is provided hereinbelow with reference to the sequence listing part.

[3326] GAM236 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM236 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3327] An enzyme complex designated DICER COMPLEX, dices the GAM236 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM236 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM236 RNA is designated SEQ ID:3495, and is provided hereinbelow with reference to the sequence listing part.

[3328] GAM236 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM236 target RNA, herein designated GAM TARGET RNA. GAM236 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3329] GAM236 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM236 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM236 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM236 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM236 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3330] The complementary binding of GAM236 RNA, herein designated GAM RNA, to target binding sites on GAM236 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM236 target RNA, herein designated GAM TARGET RNA, into GAM236 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3331] It is appreciated that GAM236 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM236 target genes. The mRNA of each one of this plurality of GAM236 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM236 RNA, herein designated GAM RNA, and which when bound by GAM236 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM236 target proteins.

[3332] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM236 gene, herein designated GAM GENE, on one or more GAM236 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3333] It is yet further appreciated that specific functions, and accordingly utilities, of GAM236 correlate with, and may be deduced from, the identity of the target genes which GAM236 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3334] Nucleotide sequences of the GAM236 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM236 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM236 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM236 are further described hereinbelow with reference to Table Table1.

[3335] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM236 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3336]

[3337] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 237 (GAM237) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3338] GAM237 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM237 was detected is described hereinabove with reference to Figs. 2-8.

[3339] GAM237 gene, herein designated GAM GENE, and GAM237 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3340] GAM237 gene, herein designated GAM GENE, encodes a GAM237 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM237 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM237 precursor RNA is designated SEQ ID:3506, and is provided hereinbelow with reference to the sequence listing part.

[3341] GAM237 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM237 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3342] An enzyme complex designated DICER COMPLEX, dices the GAM237 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM237 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM237 RNA is designated SEQ ID:3507, and is provided

hereinbelow with reference to the sequence listing part.

[3343] GAM237 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM237 target RNA, herein designated GAM TARGET RNA. GAM237 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3344] GAM237 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM237 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM237 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM237 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM237 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3345] The complementary binding of GAM237 RNA, herein designated GAM RNA, to target binding sites on GAM237 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM237 target RNA, herein designated GAM TARGET RNA, into GAM237 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3346] It is appreciated that GAM237 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM237 target genes. The mRNA of each one of this plurality of GAM237 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM237 RNA, herein designated GAM RNA, and which when bound by GAM237 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM237 tar-

get proteins.

[3347] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM237 gene, herein designated GAM GENE, on one or more GAM237 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3348] It is yet further appreciated that specific functions, and accordingly utilities, of GAM237 correlate with, and may be deduced from, the identity of the target genes which GAM237 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3349] Nucleotide sequences of the GAM237 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM237 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM237 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM237 are further described hereinbelow with reference to Table Table1.

[3350] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM237 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3351]

[3352] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 238 (GAM238) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3353] GAM238 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM238 was detected is described hereinabove with reference to Figs. 2-8.

[3354] GAM238 gene, herein designated GAM GENE, and GAM238 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3355] GAM238 gene, herein designated GAM GENE, encodes a GAM238 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM238 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM238 precursor RNA is designated SEQ ID:3522, and is provided hereinbelow with reference to the sequence listing part.

[3356] GAM238 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM238 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3357] An enzyme complex designated DICER COMPLEX, dices

the GAM238 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM238 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM238 RNA is designated SEQ ID:3523, and is provided hereinbelow with reference to the sequence listing part.

[3358] GAM238 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM238 target RNA, herein designated GAM TARGET RNA. GAM238 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3359] GAM238 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM238 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM238

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM238 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM238 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3360] The complementary binding of GAM238 RNA, herein designated GAM RNA, to target binding sites on GAM238 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM238 target RNA, herein designated GAM TARGET RNA, into GAM238 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3361] It is appreciated that GAM238 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM238 target genes. The mRNA of each one of this plurality of GAM238 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM238 RNA, herein designated GAM RNA, and which when bound by GAM238 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM238 target proteins.

[3362] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM238 gene, herein designated GAM GENE, on one or more GAM238 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3363] It is yet further appreciated that specific functions, and accordingly utilities, of GAM238 correlate with, and may be deduced from, the identity of the target genes which GAM238 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3364] Nucleotide sequences of the GAM238 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM238 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM238 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM238 are further described hereinbelow with reference to Table Table1.

[3365] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM238 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3366]

[3367] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 239 (GAM239) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3368] GAM239 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM239 was detected is described hereinabove with reference to Figs. 2-8.

[3369] GAM239 gene, herein designated GAM GENE, and GAM239 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3370] GAM239 gene, herein designated GAM GENE, encodes a GAM239 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM239 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM239 precursor RNA is designated SEQ ID:3543, and is provided hereinbelow with reference to the sequence listing part.

[3371] GAM239 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM239 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3372] An enzyme complex designated DICER COMPLEX, dices the GAM239 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM239 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM239 RNA is designated SEQ ID:3544, and is provided hereinbelow with reference to the sequence listing part.

[3373] GAM239 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM239 target RNA, herein designated GAM TARGET RNA. GAM239 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3374] GAM239 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM239 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM239 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM239 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM239 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[3375] The complementary binding of GAM239 RNA, herein designated GAM RNA, to target binding sites on GAM239 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM239 target RNA, herein designated GAM TARGET RNA, into GAM239 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3376] It is appreciated that GAM239 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM239 target genes. The mRNA of each one of this plurality of GAM239 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM239 RNA, herein designated GAM RNA, and which when bound by GAM239 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM239 target proteins.

[3377] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM239 gene, herein designated GAM GENE, on one or

more GAM239 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3378] It is yet further appreciated that specific functions, and accordingly utilities, of GAM239 correlate with, and may be deduced from, the identity of the target genes which GAM239 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3379] Nucleotide sequences of the GAM239 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM239 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM239 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM239 are further de-

scribed hereinbelow with reference to Table Table1.

[3380] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM239 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3381]

[3382] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 240 (GAM240) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3383] GAM240 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM240 was detected is described hereinabove with reference to Figs. 2-8.

[3384] GAM240 gene, herein designated GAM GENE, and GAM240 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3385] GAM240 gene, herein designated GAM GENE, encodes a GAM240 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM240 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM240 precursor RNA is designated SEQ ID:3570, and is provided hereinbelow with reference to the sequence listing part.

[3386] GAM240 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM240 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3387] An enzyme complex designated DICER COMPLEX, dices the GAM240 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM240 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM240 RNA is designated SEQ ID:3571, and is provided hereinbelow with reference to the sequence listing part.

[3388] GAM240 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM240 target RNA, herein designated GAM TARGET RNA. GAM240 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3389] GAM240 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM240 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM240 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM240 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM240 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3390] The complementary binding of GAM240 RNA, herein designated GAM RNA, to target binding sites on GAM240 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM240 target RNA, herein designated GAM TARGET RNA, into GAM240 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3391] It is appreciated that GAM240 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM240 target genes. The mRNA of each one of this plurality of GAM240 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM240 RNA, herein designated GAM RNA, and which when bound by GAM240 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM240 target proteins.

[3392] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM240 gene, herein designated GAM GENE, on one or more GAM240 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3393] It is yet further appreciated that specific functions, and accordingly utilities, of GAM240 correlate with, and may

be deduced from, the identity of the target genes which GAM240 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3394] Nucleotide sequences of the GAM240 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM240 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM240 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM240 are further described hereinbelow with reference to Table Table1.

[3395] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM240 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3396]

[3397] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 241 (GAM241) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3398] GAM241 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM241 was detected is described hereinabove with reference to Figs. 2-8.

[3399] GAM241 gene, herein designated GAM GENE, and GAM241 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3400] GAM241 gene, herein designated GAM GENE, encodes a GAM241 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM241 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM241 precursor RNA is designated SEQ ID:3578, and is provided hereinbelow with reference to the sequence listing part.

[3401] GAM241 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM241 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3402] An enzyme complex designated DICER COMPLEX, dices the GAM241 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM241 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM241 RNA is designated SEQ ID:3579, and is provided hereinbelow with reference to the sequence listing part.

[3403] GAM241 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM241 target RNA, herein designated GAM TARGET RNA. GAM241 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3404] GAM241 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM241 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM241 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM241 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM241 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3405] The complementary binding of GAM241 RNA, herein designated GAM RNA, to target binding sites on GAM241 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM241 target RNA, herein designated GAM TARGET RNA, into GAM241 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3406] It is appreciated that GAM241 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM241 target genes. The mRNA of each one of this plurality of GAM241 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM241 RNA, herein designated GAM RNA, and which when bound by GAM241 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM241 target proteins.

[3407] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM241 gene, herein designated GAM GENE, on one or more GAM241 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3408] It is yet further appreciated that specific functions, and accordingly utilities, of GAM241 correlate with, and may be deduced from, the identity of the target genes which GAM241 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3409] Nucleotide sequences of the GAM241 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM241 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM241 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM241 are further described hereinbelow with reference to Table Table1.

[3410] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM241 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3411]

[3412] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 242 (GAM242) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3413] GAM242 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM242 was detected is described hereinabove with reference to Figs. 2-8.

[3414] GAM242 gene, herein designated GAM GENE, and GAM242 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3415] GAM242 gene, herein designated GAM GENE, encodes a GAM242 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM242 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM242 precursor RNA is desig-

nated SEQ ID:3584, and is provided hereinbelow with reference to the sequence listing part.

[3416] GAM242 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM242 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3417] An enzyme complex designated DICER COMPLEX, dices the GAM242 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM242 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 20%) nucleotide sequence of GAM242 RNA is designated SEQ ID:3585, and is provided hereinbelow with reference to the sequence listing part.

[3418] GAM242 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM242 target RNA, herein designated GAM TARGET RNA. GAM242 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3419] GAM242 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM242 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM242 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM242 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM242

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3420] The complementary binding of GAM242 RNA, herein designated GAM RNA, to target binding sites on GAM242 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM242 target RNA, herein designated GAM TARGET RNA, into GAM242 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3421] It is appreciated that GAM242 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM242 target genes. The mRNA of each one of this plurality of GAM242 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM242 RNA, herein designated GAM RNA, and which when bound by GAM242 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM242 target proteins.

[3422] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM242 gene, herein designated GAM GENE, on one or more GAM242 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3423] It is yet further appreciated that specific functions, and accordingly utilities, of GAM242 correlate with, and may be deduced from, the identity of the target genes which GAM242 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3424] Nucleotide sequences of the GAM242 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM242 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM242 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM242 are further described hereinbelow with reference to Table Table1.

[3425] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM242 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3426]

[3427] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 243 (GAM243) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3428] GAM243 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM243 was detected is described hereinabove with reference to Figs. 2-8.

[3429] GAM243 gene, herein designated GAM GENE, and

GAM243 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3430] GAM243 gene, herein designated GAM GENE, encodes a GAM243 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM243 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM243 precursor RNA is designated SEQ ID:3593, and is provided hereinbelow with reference to the sequence listing part.

[3431] GAM243 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM243 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3432] An enzyme complex designated DICER COMPLEX, dices the GAM243 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM243 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 45%) nucleotide sequence of GAM243 RNA is designated SEQ ID:3594, and is provided hereinbelow with reference to the sequence listing part.

[3433] GAM243 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM243 target RNA, herein designated GAM TARGET RNA. GAM243 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3434] GAM243 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM243 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM243 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM243 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM243 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3435] The complementary binding of GAM243 RNA, herein designated GAM RNA, to target binding sites on GAM243 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM243 target RNA, herein designated GAM TARGET RNA, into GAM243 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3436] It is appreciated that GAM243 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM243 target genes. The mRNA of each one of this plurality of GAM243 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM243 RNA, herein designated GAM RNA, and which when bound by GAM243 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM243 target proteins.

[3437] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM243 gene, herein designated GAM GENE, on one or more GAM243 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3438] It is yet further appreciated that specific functions, and accordingly utilities, of GAM243 correlate with, and may be deduced from, the identity of the target genes which GAM243 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3439] Nucleotide sequences of the GAM243 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM243 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM243 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM243 are further described hereinbelow with reference to Table Table1.

[3440] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM243 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3441]

[3442] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 244 (GAM244) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3443] GAM244 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM244 was detected is described hereinabove with reference to Figs. 2-8.

[3444] GAM244 gene, herein designated GAM GENE, and GAM244 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3445] GAM244 gene, herein designated GAM GENE, encodes a GAM244 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM244 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM244 precursor RNA is designated SEQ ID:3622, and is provided hereinbelow with reference to the sequence listing part.

[3446] GAM244 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM244 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3447] An enzyme complex designated DICER COMPLEX, dices the GAM244 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM244 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM244 RNA is designated SEQ ID:3623, and is provided hereinbelow with reference to the sequence listing part.

[3448] GAM244 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM244 target RNA, herein designated GAM TARGET RNA. GAM244 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3449] GAM244 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM244 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM244 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM244 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM244 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3450] The complementary binding of GAM244 RNA, herein designated GAM RNA, to target binding sites on GAM244 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM244 target RNA, herein designated GAM TARGET RNA, into GAM244 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3451] It is appreciated that GAM244 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM244 target genes. The mRNA of each one of this plurality of GAM244 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM244 RNA, herein designated GAM RNA, and which when bound by GAM244 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM244 target proteins.

[3452] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM244 gene, herein designated GAM GENE, on one or more GAM244 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3453] It is yet further appreciated that specific functions, and accordingly utilities, of GAM244 correlate with, and may be deduced from, the identity of the target genes which GAM244 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3454] Nucleotide sequences of the GAM244 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM244 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM244 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM244 are further described hereinbelow with reference to Table Table1.

[3455] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM244 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3456]

[3457] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 245 (GAM245) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3458] GAM245 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM245 was detected is described hereinabove with reference to Figs. 2-8.

[3459] GAM245 gene, herein designated GAM GENE, and GAM245 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3460] GAM245 gene, herein designated GAM GENE, encodes a GAM245 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM245 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM245 precursor RNA is designated SEQ ID:3658, and is provided hereinbelow with reference to the sequence listing part.

[3461] GAM245 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM245 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3462] An enzyme complex designated DICER COMPLEX, dices the GAM245 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM245 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM245 RNA is designated SEQ ID:3623, and is provided hereinbelow with reference to the sequence listing part.

[3463] GAM245 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM245 target RNA, herein designated GAM TARGET RNA. GAM245 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3464] GAM245 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM245 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM245 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM245 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM245 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3465] The complementary binding of GAM245 RNA, herein designated GAM RNA, to target binding sites on GAM245 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM245 target RNA, herein designated GAM TARGET RNA, into GAM245 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3466] It is appreciated that GAM245 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM245 target genes. The mRNA of each one of this plurality of GAM245 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM245 RNA,

herein designated GAM RNA, and which when bound by GAM245 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM245 target proteins.

[3467] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM245 gene, herein designated GAM GENE, on one or more GAM245 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3468] It is yet further appreciated that specific functions, and accordingly utilities, of GAM245 correlate with, and may be deduced from, the identity of the target genes which

GAM245 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3469] Nucleotide sequences of the GAM245 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM245 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM245 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM245 are further described hereinbelow with reference to Table Table1.

[3470] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM245 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3471]

[3472] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 246 (GAM246) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3473] GAM246 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM246 was detected is described hereinabove with reference to Figs. 2-8.

[3474] GAM246 gene, herein designated GAM GENE, and GAM246 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3475] GAM246 gene, herein designated GAM GENE, encodes a GAM246 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM246 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM246 precursor RNA is designated SEQ ID:3660, and is provided hereinbelow with reference to the sequence listing part.

[3476] GAM246 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM246 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[3477] An enzyme complex designated DICER COMPLEX, dices the GAM246 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM246 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM246 RNA is designated SEQ ID:3661, and is provided hereinbelow with reference to the sequence listing part.

[3478] GAM246 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM246 target RNA, herein designated GAM TARGET RNA.
GAM246 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3479] GAM246 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM246 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM246 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM246 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM246 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3480] The complementary binding of GAM246 RNA, herein designated GAM RNA, to target binding sites on GAM246 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM246 target RNA, herein desig-

nated GAM TARGET RNA, into GAM246 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3481] It is appreciated that GAM246 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM246 target genes. The mRNA of each one of this plurality of GAM246 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM246 RNA, herein designated GAM RNA, and which when bound by GAM246 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM246 target proteins.

[3482] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM246 gene, herein designated GAM GENE, on one or more GAM246 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3483] It is yet further appreciated that specific functions, and accordingly utilities, of GAM246 correlate with, and may be deduced from, the identity of the target genes which GAM246 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3484] Nucleotide sequences of the GAM246 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM246 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM246 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM246 are further described hereinbelow with reference to Table Table1.

[3485] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM246 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[3486]

[3487] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 247 (GAM247) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3488] GAM247 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM247 was detected is described hereinabove with reference to Figs. 2-8.

[3489] GAM247 gene, herein designated GAM GENE, and GAM247 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3490] GAM247 gene, herein designated GAM GENE, encodes a GAM247 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM247 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM247 precursor RNA is designated SEQ ID:3675, and is provided hereinbelow with ref-

erence to the sequence listing part.

[3491] GAM247 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM247 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3492] An enzyme complex designated DICER COMPLEX, dices the GAM247 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM247 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM247 RNA is designated SEQ ID:3676, and is provided hereinbelow with reference to the sequence listing part.

[3493] GAM247 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM247 target RNA, herein designated GAM TARGET RNA.

GAM247 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3494] GAM247 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM247 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM247 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM247 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM247 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3495] The complementary binding of GAM247 RNA, herein designated GAM RNA, to target binding sites on GAM247 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM247 target RNA, herein designated GAM TARGET RNA, into GAM247 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3496] It is appreciated that GAM247 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM247 target genes. The mRNA of each one of this plurality of GAM247 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM247 RNA, herein designated GAM RNA, and which when bound by GAM247 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM247 target proteins.

[3497] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM247 gene, herein designated GAM GENE, on one or more GAM247 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3498] It is yet further appreciated that specific functions, and accordingly utilities, of GAM247 correlate with, and may be deduced from, the identity of the target genes which GAM247 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3499] Nucleotide sequences of the GAM247 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM247 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM247 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM247 are further described hereinbelow with reference to Table Table1.

[3500] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM247 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3501]

[3502] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 248 (GAM248) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3503] GAM248 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM248 was detected is described hereinabove with reference to Figs. 2-8.

[3504] GAM248 gene, herein designated GAM GENE, and GAM248 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[3505] GAM248 gene, herein designated GAM GENE, encodes a GAM248 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM248 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM248 precursor RNA is designated SEQ ID:3696, and is provided hereinbelow with reference to the sequence listing part.

[3506] GAM248 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM248 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3507] An enzyme complex designated DICER COMPLEX, dices the GAM248 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM248 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 78%) nucleotide sequence of GAM248 RNA is designated SEQ ID:3697, and is provided hereinbelow with reference to the sequence listing part.

[3508] GAM248 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM248 target RNA, herein designated GAM TARGET RNA. GAM248 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3509] GAM248 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM248 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM248 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM248 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM248 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3510] The complementary binding of GAM248 RNA, herein designated GAM RNA, to target binding sites on GAM248 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM248 target RNA, herein designated GAM TARGET RNA, into GAM248 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3511] It is appreciated that GAM248 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM248 target genes. The mRNA of each one of this plurality of GAM248 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM248 RNA, herein designated GAM RNA, and which when bound by GAM248 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM248 target proteins.

[3512] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM248 gene, herein designated GAM GENE, on one or more GAM248 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[3513] It is yet further appreciated that specific functions, and accordingly utilities, of GAM248 correlate with, and may be deduced from, the identity of the target genes which GAM248 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3514] Nucleotide sequences of the GAM248 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM248 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM248 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM248 are further described hereinbelow with reference to Table Table1.

[3515] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM248 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3516]

[3517] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

249 (GAM249) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3518] GAM249 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM249 was detected is described hereinabove with reference to Figs. 2-8.

[3519] GAM249 gene, herein designated GAM GENE, and GAM249 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3520] GAM249 gene, herein designated GAM GENE, encodes a GAM249 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM249 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM249 precursor RNA is designated SEQ ID:3709, and is provided hereinbelow with reference to the sequence listing part.

[3521] GAM249 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM249 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3522] An enzyme complex designated DICER COMPLEX, dices the GAM249 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM249 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM249 RNA is designated SEQ ID:3710, and is provided hereinbelow with reference to the sequence listing part.

[3523] GAM249 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM249 target RNA, herein designated GAM TARGET RNA. GAM249 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3524] GAM249 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM249 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM249 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM249 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM249 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3525] The complementary binding of GAM249 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM249 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM249 target RNA, herein designated GAM TARGET RNA, into GAM249 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3526] It is appreciated that GAM249 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM249 target genes. The mRNA of each one of this plurality of GAM249 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM249 RNA, herein designated GAM RNA, and which when bound by GAM249 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM249 target proteins.

[3527] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM249 gene, herein designated GAM GENE, on one or more GAM249 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3528] It is yet further appreciated that specific functions, and accordingly utilities, of GAM249 correlate with, and may be deduced from, the identity of the target genes which GAM249 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3529] Nucleotide sequences of the GAM249 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM249 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM249 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM249 are further described hereinbelow with reference to Table Table1.

[3530] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM249 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3531]

[3532] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 250 (GAM250) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3533] GAM250 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM250 was detected is described hereinabove with reference to Figs. 2-8.

[3534] GAM250 gene, herein designated GAM GENE, and GAM250 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3535] GAM250 gene, herein designated GAM GENE, encodes a GAM250 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM250 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM250 precursor RNA is designated SEQ ID:3717, and is provided hereinbelow with reference to the sequence listing part.

[3536] GAM250 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM250 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3537] An enzyme complex designated DICER COMPLEX, dices the GAM250 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM250 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 63%) nucleotide sequence of GAM250 RNA is designated SEQ ID:3718, and is provided hereinbelow with reference to the sequence listing part.

[3538] GAM250 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM250 target RNA, herein designated GAM TARGET RNA. GAM250 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3539] GAM250 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM250 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM250 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM250 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM250 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3540] The complementary binding of GAM250 RNA, herein designated GAM RNA, to target binding sites on GAM250 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM250 target RNA, herein designated GAM TARGET RNA, into GAM250 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3541] It is appreciated that GAM250 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM250 target genes. The mRNA of each one of this plurality of GAM250 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM250 RNA, herein designated GAM RNA, and which when bound by

GAM250 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM250 target proteins.

[3542] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM250 gene, herein designated GAM GENE, on one or more GAM250 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3543] It is yet further appreciated that specific functions, and accordingly utilities, of GAM250 correlate with, and may be deduced from, the identity of the target genes which GAM250 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[3544] Nucleotide sequences of the GAM250 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM250 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM250 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM250 are further described hereinbelow with reference to Table Table1.

[3545] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM250 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3546]

[3547] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 251 (GAM251) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3548] GAM251 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM251 was detected is described hereinabove with reference to Figs. 2-8.

[3549] GAM251 gene, herein designated GAM GENE, and GAM251 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3550] GAM251 gene, herein designated GAM GENE, encodes a GAM251 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM251 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM251 precursor RNA is designated SEQ ID:3735, and is provided hereinbelow with reference to the sequence listing part.

[3551] GAM251 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM251 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[3552] An enzyme complex designated DICER COMPLEX, dices the GAM251 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM251 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 28%) nucleotide sequence of GAM251 RNA is designated SEQ ID:3736, and is provided hereinbelow with reference to the sequence listing part.

[3553] GAM251 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM251 target RNA, herein designated GAM TARGET RNA. GAM251 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3554] GAM251 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM251 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM251 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM251 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM251 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3555] The complementary binding of GAM251 RNA, herein designated GAM RNA, to target binding sites on GAM251 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM251 target RNA, herein designated GAM TARGET RNA, into GAM251 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3556] It is appreciated that GAM251 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM251 target genes. The mRNA of each one of this plurality of GAM251 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM251 RNA, herein designated GAM RNA, and which when bound by GAM251 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM251 target proteins.

[3557] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM251 gene, herein designated GAM GENE, on one or more GAM251 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3558] It is yet further appreciated that specific functions, and accordingly utilities, of GAM251 correlate with, and may be deduced from, the identity of the target genes which GAM251 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3559] Nucleotide sequences of the GAM251 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM251 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM251 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM251 are further described hereinbelow with reference to Table Table1.

[3560] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM251 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3561]

[3562] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 252 (GAM252) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3563] GAM252 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM252 was detected is described hereinabove with reference to Figs. 2-8.

[3564] GAM252 gene, herein designated GAM GENE, and GAM252 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3565] GAM252 gene, herein designated GAM GENE, encodes a GAM252 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM252 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM252 precursor RNA is designated SEQ ID:3745, and is provided hereinbelow with reference to the sequence listing part.

[3566] GAM252 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM252 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3567] An enzyme complex designated DICER COMPLEX, dices the GAM252 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM252 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM252 RNA is designated SEQ ID:3746, and is provided hereinbelow with reference to the sequence listing part.

[3568] GAM252 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM252

target RNA, herein designated GAM TARGET RNA.

GAM252 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3569] GAM252 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM252 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM252 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM252 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM252 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3570] The complementary binding of GAM252 RNA, herein designated GAM RNA, to target binding sites on GAM252 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM252 target RNA, herein designated GAM TARGET RNA, into GAM252 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3571] It is appreciated that GAM252 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM252 target genes. The mRNA of each one of this plurality of GAM252 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM252 RNA, herein designated GAM RNA, and which when bound by GAM252 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM252 target proteins.

[3572] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM252 gene, herein designated GAM GENE, on one or more GAM252 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3573] It is yet further appreciated that specific functions, and accordingly utilities, of GAM252 correlate with, and may be deduced from, the identity of the target genes which GAM252 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3574] Nucleotide sequences of the GAM252 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM252 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM252 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM252 are further described hereinbelow with reference to Table Table1.

[3575] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM252 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3576]

[3577] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 253 (GAM253) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3578] GAM253 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM253 was detected is described hereinabove with reference to Figs. 2-8.

[3579] GAM253 gene, herein designated GAM GENE, and GAM253 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3580] GAM253 gene, herein designated GAM GENE, encodes a GAM253 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM253 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM253 precursor RNA is designated SEQ ID:3761, and is provided hereinbelow with reference to the sequence listing part.

[3581] GAM253 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM253 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3582] An enzyme complex designated DICER COMPLEX, dices the GAM253 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM253 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM253 RNA is designated SEQ ID:3762, and is provided hereinbelow with reference to the sequence listing part.

[3583] GAM253 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM253 target RNA, herein designated GAM TARGET RNA. GAM253 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3584] GAM253 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM253 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM253 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM253 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM253 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3585] The complementary binding of GAM253 RNA, herein designated GAM RNA, to target binding sites on GAM253 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM253 target RNA, herein designated GAM TARGET RNA, into GAM253 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3586] It is appreciated that GAM253 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM253 target genes. The mRNA of each one of this plu-

rality of GAM253 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM253 RNA, herein designated GAM RNA, and which when bound by GAM253 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM253 target proteins.

[3587] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM253 gene, herein designated GAM GENE, on one or more GAM253 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3588] It is yet further appreciated that specific functions, and accordingly utilities, of GAM253 correlate with, and may be deduced from, the identity of the target genes which GAM253 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3589] Nucleotide sequences of the GAM253 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM253 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM253 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM253 are further described hereinbelow with reference to Table Table1.

[3590] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM253 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3591]

[3592] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 254 (GAM254) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[3593] GAM254 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM254 was detected is described hereinabove with reference to Figs. 2-8.

[3594] GAM254 gene, herein designated GAM GENE, and GAM254 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3595] GAM254 gene, herein designated GAM GENE, encodes a GAM254 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM254 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM254 precursor RNA is designated SEQ ID:3779, and is provided hereinbelow with reference to the sequence listing part.

[3596] GAM254 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM254 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3597] An enzyme complex designated DICER COMPLEX, dices the GAM254 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM254 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM254 RNA is designated SEQ ID:3780, and is provided hereinbelow with reference to the sequence listing part.

[3598] GAM254 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM254 target RNA, herein designated GAM TARGET RNA.
GAM254 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[3599] GAM254 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM254 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM254 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM254 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM254 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3600] The complementary binding of GAM254 RNA, herein designated GAM RNA, to target binding sites on GAM254 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM254 target RNA, herein designated GAM TARGET RNA, into GAM254 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3601] It is appreciated that GAM254 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM254 target genes. The mRNA of each one of this plurality of GAM254 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM254 RNA, herein designated GAM RNA, and which when bound by GAM254 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM254 target proteins.

[3602] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM254 gene, herein designated GAM GENE, on one or more GAM254 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3603] It is yet further appreciated that specific functions, and accordingly utilities, of GAM254 correlate with, and may be deduced from, the identity of the target genes which GAM254 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3604] Nucleotide sequences of the GAM254 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM254 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM254 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM254 are further described hereinbelow with reference to Table Table1.

[3605] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM254 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3606]

[3607] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 255 (GAM255) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3608] GAM255 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM255 was detected is described hereinabove with reference to Figs. 2-8.

[3609] GAM255 gene, herein designated GAM GENE, and GAM255 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3610] GAM255 gene, herein designated GAM GENE, encodes a GAM255 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM255 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM255 precursor RNA is designated SEQ ID:3815, and is provided hereinbelow with reference to the sequence listing part.

[3611] GAM255 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM255 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3612] An enzyme complex designated DICER COMPLEX, dices the GAM255 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM255 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of

GAM255 RNA is designated SEQ ID:3816, and is provided hereinbelow with reference to the sequence listing part.

[3613] GAM255 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM255 target RNA, herein designated GAM TARGET RNA. GAM255 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3614] GAM255 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM255 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM255 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM255 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM255 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3615] The complementary binding of GAM255 RNA, herein designated GAM RNA, to target binding sites on GAM255 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM255 target RNA, herein designated GAM TARGET RNA, into GAM255 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3616] It is appreciated that GAM255 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM255 target genes. The mRNA of each one of this plurality of GAM255 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM255 RNA, herein designated GAM RNA, and which when bound by GAM255 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM255 target proteins.

[3617] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM255 gene, herein designated GAM GENE, on one or more GAM255 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3618] It is yet further appreciated that specific functions, and accordingly utilities, of GAM255 correlate with, and may be deduced from, the identity of the target genes which GAM255 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3619] Nucleotide sequences of the GAM255 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM255 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM255 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM255 are further described hereinbelow with reference to Table Table1.

[3620] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM255 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3621]

[3622] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 256 (GAM256) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3623] GAM256 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM256 was detected is described hereinabove

with reference to Figs. 2-8.

[3624] GAM256 gene, herein designated GAM GENE, and GAM256 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3625] GAM256 gene, herein designated GAM GENE, encodes a GAM256 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM256 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM256 precursor RNA is designated SEQ ID:3848, and is provided hereinbelow with reference to the sequence listing part.

[3626] GAM256 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM256 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3627] An enzyme complex designated DICER COMPLEX, dices the GAM256 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM256 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM256 RNA is designated SEQ ID:3849, and is provided hereinbelow with reference to the sequence listing part.

[3628] GAM256 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM256 target RNA, herein designated GAM TARGET RNA. GAM256 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3629] GAM256 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM256 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM256 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM256 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM256 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3630] The complementary binding of GAM256 RNA, herein designated GAM RNA, to target binding sites on GAM256 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM256 target RNA, herein designated GAM TARGET RNA, into GAM256 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[3631] It is appreciated that GAM256 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM256 target genes. The mRNA of each one of this plurality of GAM256 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM256 RNA, herein designated GAM RNA, and which when bound by GAM256 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM256 target proteins.

[3632] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM256 gene, herein designated GAM GENE, on one or more GAM256 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3633] It is yet further appreciated that specific functions, and accordingly utilities, of GAM256 correlate with, and may be deduced from, the identity of the target genes which GAM256 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3634] Nucleotide sequences of the GAM256 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM256 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM256 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM256 are further described hereinbelow with reference to Table Table1.

[3635] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM256 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3636]

[3637] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 257 (GAM257) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3638] GAM257 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM257 was detected is described hereinabove with reference to Figs. 2-8.

[3639] GAM257 gene, herein designated GAM GENE, and GAM257 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3640] GAM257 gene, herein designated GAM GENE, encodes a GAM257 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM257 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM257 precursor RNA is designated SEQ ID:3858, and is provided hereinbelow with reference to the sequence listing part.

[3641] GAM257 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM257 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3642] An enzyme complex designated DICER COMPLEX, dices the GAM257 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM257 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 32%) nucleotide sequence of GAM257 RNA is designated SEQ ID:3859, and is provided hereinbelow with reference to the sequence listing part.

[3643] GAM257 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM257 target RNA, herein designated GAM TARGET RNA.

GAM257 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3644] GAM257 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM257 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM257 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM257 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM257 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3645] The complementary binding of GAM257 RNA, herein designated GAM RNA, to target binding sites on GAM257 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM257 target RNA, herein designated GAM TARGET RNA, into GAM257 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3646] It is appreciated that GAM257 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM257 target genes. The mRNA of each one of this plurality of GAM257 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM257 RNA, herein designated GAM RNA, and which when bound by GAM257 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM257 target proteins.

[3647] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM257 gene, herein designated GAM GENE, on one or more GAM257 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3648] It is yet further appreciated that specific functions, and accordingly utilities, of GAM257 correlate with, and may be deduced from, the identity of the target genes which GAM257 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3649] Nucleotide sequences of the GAM257 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM257 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM257 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM257 are further described hereinbelow with reference to Table Table1.

[3650] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM257 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3651]

[3652] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 258 (GAM258) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3653] GAM258 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM258 was detected is described hereinabove with reference to Figs. 2-8.

[3654] GAM258 gene, herein designated GAM GENE, and GAM258 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3655] GAM258 gene, herein designated GAM GENE, encodes a

GAM258 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM258 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM258 precursor RNA is designated SEQ ID:3884, and is provided hereinbelow with reference to the sequence listing part.

[3656] GAM258 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM258 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3657] An enzyme complex designated DICER COMPLEX, dices the GAM258 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM258 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 25%) nucleotide sequence of GAM258 RNA is designated SEQ ID:3885, and is provided hereinbelow with reference to the sequence listing part.

[3658] GAM258 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM258 target RNA, herein designated GAM TARGET RNA. GAM258 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3659] GAM258 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM258 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM258 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM258 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM258 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3660] The complementary binding of GAM258 RNA, herein designated GAM RNA, to target binding sites on GAM258 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM258 target RNA, herein designated GAM TARGET RNA, into GAM258 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3661] It is appreciated that GAM258 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM258 target genes. The mRNA of each one of this plurality of GAM258 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM258 RNA, herein designated GAM RNA, and which when bound by GAM258 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM258 target proteins.

[3662] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM258 gene, herein designated GAM GENE, on one or more GAM258 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3663] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM258 correlate with, and may be deduced from, the identity of the target genes which GAM258 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3664] Nucleotide sequences of the GAM258 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM258 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM258 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM258 are further described hereinbelow with reference to Table Table1.

[3665] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM258 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3666]

[3667] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 259 (GAM259) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[3668] GAM259 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM259 was detected is described hereinabove with reference to Figs. 2-8.

[3669] GAM259 gene, herein designated GAM GENE, and GAM259 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3670] GAM259 gene, herein designated GAM GENE, encodes a GAM259 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM259 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM259 precursor RNA is designated SEQ ID:3899, and is provided hereinbelow with reference to the sequence listing part.

[3671] GAM259 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM259 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3672] An enzyme complex designated DICER COMPLEX, dices the GAM259 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM259 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM259 RNA is designated SEQ ID:3900, and is provided hereinbelow with reference to the sequence listing part.

[3673] GAM259 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM259 target RNA, herein designated GAM TARGET RNA. GAM259 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3674] GAM259 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM259 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM259 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM259 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM259 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3675] The complementary binding of GAM259 RNA, herein designated GAM RNA, to target binding sites on GAM259 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM259 target RNA, herein designated GAM TARGET RNA, into GAM259 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3676] It is appreciated that GAM259 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM259 target genes. The mRNA of each one of this plurality of GAM259 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM259 RNA, herein designated GAM RNA, and which when bound by GAM259 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM259 target proteins.

[3677] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM259 gene, herein designated GAM GENE, on one or more GAM259 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3678] It is yet further appreciated that specific functions, and accordingly utilities, of GAM259 correlate with, and may be deduced from, the identity of the target genes which GAM259 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3679] Nucleotide sequences of the GAM259 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM259 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM259 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM259 are further described hereinbelow with reference to Table Table1.

[3680] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM259 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3681]

[3682] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 260 (GAM260) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3683] GAM260 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM260 was detected is described hereinabove with reference to Figs. 2-8.

[3684] GAM260 gene, herein designated GAM GENE, and GAM260 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3685] GAM260 gene, herein designated GAM GENE, encodes a GAM260 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM260 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM260 precursor RNA is designated SEQ ID:3909, and is provided hereinbelow with reference to the sequence listing part.

[3686] GAM260 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM260 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3687] An enzyme complex designated DICER COMPLEX, dices the GAM260 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM260 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 81%) nucleotide sequence of GAM260 RNA is designated SEQ ID:3910, and is provided

hereinbelow with reference to the sequence listing part.

[3688] GAM260 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM260 target RNA, herein designated GAM TARGET RNA.
GAM260 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3689] GAM260 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM260 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM260 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM260 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM260 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3690] The complementary binding of GAM260 RNA, herein designated GAM RNA, to target binding sites on GAM260 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM260 target RNA, herein designated GAM TARGET RNA, into GAM260 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3691] It is appreciated that GAM260 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM260 target genes. The mRNA of each one of this plurality of GAM260 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM260 RNA, herein designated GAM RNA, and which when bound by GAM260 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM260 tar-

get proteins.

[3692] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM260 gene, herein designated GAM GENE, on one or more GAM260 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3693] It is yet further appreciated that specific functions, and accordingly utilities, of GAM260 correlate with, and may be deduced from, the identity of the target genes which GAM260 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3694] Nucleotide sequences of the GAM260 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM260 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM260 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM260 are further described hereinbelow with reference to Table Table1.

[3695] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM260 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3696]

[3697] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 261 (GAM261) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3698] GAM261 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM261 was detected is described hereinabove with reference to Figs. 2-8.

[3699] GAM261 gene, herein designated GAM GENE, and GAM261 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3700] GAM261 gene, herein designated GAM GENE, encodes a GAM261 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM261 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM261 precursor RNA is designated SEQ ID:3917, and is provided hereinbelow with reference to the sequence listing part.

[3701] GAM261 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM261 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3702] An enzyme complex designated DICER COMPLEX, dices

the GAM261 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM261 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM261 RNA is designated SEQ ID:3918, and is provided hereinbelow with reference to the sequence listing part.

[3703] GAM261 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM261 target RNA, herein designated GAM TARGET RNA. GAM261 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3704] GAM261 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM261 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM261

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM261 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM261 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3705] The complementary binding of GAM261 RNA, herein designated GAM RNA, to target binding sites on GAM261 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM261 target RNA, herein designated GAM TARGET RNA, into GAM261 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3706] It is appreciated that GAM261 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM261 target genes. The mRNA of each one of this plurality of GAM261 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM261 RNA, herein designated GAM RNA, and which when bound by GAM261 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM261 target proteins.

[3707] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM261 gene, herein designated GAM GENE, on one or more GAM261 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3708] It is yet further appreciated that specific functions, and accordingly utilities, of GAM261 correlate with, and may be deduced from, the identity of the target genes which GAM261 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3709] Nucleotide sequences of the GAM261 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM261 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM261 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM261 are further described hereinbelow with reference to Table Table1.

[3710] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM261 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3711]

[3712] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 262 (GAM262) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3713] GAM262 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM262 was detected is described hereinabove with reference to Figs. 2-8.

[3714] GAM262 gene, herein designated GAM GENE, and GAM262 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3715] GAM262 gene, herein designated GAM GENE, encodes a GAM262 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM262 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM262 precursor RNA is designated SEQ ID:3922, and is provided hereinbelow with reference to the sequence listing part.

[3716] GAM262 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM262 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3717] An enzyme complex designated DICER COMPLEX, dices the GAM262 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM262 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 28%) nucleotide sequence of GAM262 RNA is designated SEQ ID:3923, and is provided hereinbelow with reference to the sequence listing part.

[3718] GAM262 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM262 target RNA, herein designated GAM TARGET RNA. GAM262 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3719] GAM262 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM262 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM262 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM262 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM262 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[3720] The complementary binding of GAM262 RNA, herein designated GAM RNA, to target binding sites on GAM262 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM262 target RNA, herein designated GAM TARGET RNA, into GAM262 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3721] It is appreciated that GAM262 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM262 target genes. The mRNA of each one of this plurality of GAM262 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM262 RNA, herein designated GAM RNA, and which when bound by GAM262 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM262 target proteins.

[3722] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM262 gene, herein designated GAM GENE, on one or

more GAM262 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3723] It is yet further appreciated that specific functions, and accordingly utilities, of GAM262 correlate with, and may be deduced from, the identity of the target genes which GAM262 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3724] Nucleotide sequences of the GAM262 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM262 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM262 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM262 are further de-

scribed hereinbelow with reference to Table Table1.

[3725] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM262 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3726]

[3727] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 263 (GAM263) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3728] GAM263 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM263 was detected is described hereinabove with reference to Figs. 2-8.

[3729] GAM263 gene, herein designated GAM GENE, and GAM263 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3730] GAM263 gene, herein designated GAM GENE, encodes a GAM263 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM263 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM263 precursor RNA is designated SEQ ID:3947, and is provided hereinbelow with reference to the sequence listing part.

[3731] GAM263 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM263 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3732] An enzyme complex designated DICER COMPLEX, dices the GAM263 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM263 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 30%) nucleotide sequence of GAM263 RNA is designated SEQ ID:3948, and is provided hereinbelow with reference to the sequence listing part.

[3733] GAM263 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM263 target RNA, herein designated GAM TARGET RNA. GAM263 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3734] GAM263 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM263 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM263 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM263 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM263 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3735] The complementary binding of GAM263 RNA, herein designated GAM RNA, to target binding sites on GAM263 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM263 target RNA, herein designated GAM TARGET RNA, into GAM263 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3736] It is appreciated that GAM263 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM263 target genes. The mRNA of each one of this plurality of GAM263 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM263 RNA, herein designated GAM RNA, and which when bound by GAM263 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM263 target proteins.

[3737] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM263 gene, herein designated GAM GENE, on one or more GAM263 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3738] It is yet further appreciated that specific functions, and accordingly utilities, of GAM263 correlate with, and may

be deduced from, the identity of the target genes which GAM263 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3739] Nucleotide sequences of the GAM263 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM263 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM263 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM263 are further described hereinbelow with reference to Table Table1.

[3740] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM263 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3741]

[3742] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 264 (GAM264) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3743] GAM264 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM264 was detected is described hereinabove with reference to Figs. 2-8.

[3744] GAM264 gene, herein designated GAM GENE, and GAM264 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3745] GAM264 gene, herein designated GAM GENE, encodes a GAM264 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM264 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM264 precursor RNA is designated SEQ ID:3961, and is provided hereinbelow with reference to the sequence listing part.

[3746] GAM264 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM264 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3747] An enzyme complex designated DICER COMPLEX, dices the GAM264 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM264 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM264 RNA is designated SEQ ID:3962, and is provided hereinbelow with reference to the sequence listing part.

[3748] GAM264 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM264 target RNA, herein designated GAM TARGET RNA. GAM264 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3749] GAM264 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM264 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM264 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM264 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM264 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3750] The complementary binding of GAM264 RNA, herein designated GAM RNA, to target binding sites on GAM264 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM264 target RNA, herein designated GAM TARGET RNA, into GAM264 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3751] It is appreciated that GAM264 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM264 target genes. The mRNA of each one of this plurality of GAM264 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM264 RNA, herein designated GAM RNA, and which when bound by GAM264 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM264 target proteins.

[3752] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM264 gene, herein designated GAM GENE, on one or more GAM264 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3753] It is yet further appreciated that specific functions, and accordingly utilities, of GAM264 correlate with, and may be deduced from, the identity of the target genes which GAM264 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3754] Nucleotide sequences of the GAM264 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM264 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM264 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM264 are further described hereinbelow with reference to Table Table1.

[3755] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM264 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3756]

[3757] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 265 (GAM265) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3758] GAM265 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM265 was detected is described hereinabove with reference to Figs. 2-8.

[3759] GAM265 gene, herein designated GAM GENE, and GAM265 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3760] GAM265 gene, herein designated GAM GENE, encodes a GAM265 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM265 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM265 precursor RNA is desig-

nated SEQ ID:3977, and is provided hereinbelow with reference to the sequence listing part.

[3761] GAM265 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM265 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3762] An enzyme complex designated DICER COMPLEX, dices the GAM265 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM265 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM265 RNA is designated SEQ ID:3978, and is provided hereinbelow with reference to the sequence listing part.

[3763] GAM265 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM265 target RNA, herein designated GAM TARGET RNA. GAM265 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3764] GAM265 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM265 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM265 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM265 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM265

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3765] The complementary binding of GAM265 RNA, herein designated GAM RNA, to target binding sites on GAM265 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM265 target RNA, herein designated GAM TARGET RNA, into GAM265 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3766] It is appreciated that GAM265 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM265 target genes. The mRNA of each one of this plurality of GAM265 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM265 RNA, herein designated GAM RNA, and which when bound by GAM265 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM265 target proteins.

[3767] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM265 gene, herein designated GAM GENE, on one or more GAM265 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3768] It is yet further appreciated that specific functions, and accordingly utilities, of GAM265 correlate with, and may be deduced from, the identity of the target genes which GAM265 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3769] Nucleotide sequences of the GAM265 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM265 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM265 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM265 are further described hereinbelow with reference to Table Table1.

[3770] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM265 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3771]

[3772] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 266 (GAM266) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3773] GAM266 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM266 was detected is described hereinabove with reference to Figs. 2-8.

[3774] GAM266 gene, herein designated GAM GENE, and

GAM266 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3775] GAM266 gene, herein designated GAM GENE, encodes a GAM266 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM266 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM266 precursor RNA is designated SEQ ID:3988, and is provided hereinbelow with reference to the sequence listing part.

[3776] GAM266 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM266 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3777] An enzyme complex designated DICER COMPLEX, dices the GAM266 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM266 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 30%) nucleotide sequence of GAM266 RNA is designated SEQ ID:3989, and is provided hereinbelow with reference to the sequence listing part.

[3778] GAM266 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM266 target RNA, herein designated GAM TARGET RNA. GAM266 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3779] GAM266 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM266 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM266 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM266 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM266 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3780] The complementary binding of GAM266 RNA, herein designated GAM RNA, to target binding sites on GAM266 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM266 target RNA, herein designated GAM TARGET RNA, into GAM266 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3781] It is appreciated that GAM266 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM266 target genes. The mRNA of each one of this plurality of GAM266 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM266 RNA, herein designated GAM RNA, and which when bound by GAM266 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM266 target proteins.

[3782] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM266 gene, herein designated GAM GENE, on one or more GAM266 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3783] It is yet further appreciated that specific functions, and accordingly utilities, of GAM266 correlate with, and may be deduced from, the identity of the target genes which GAM266 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3784] Nucleotide sequences of the GAM266 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM266 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM266 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM266 are further described hereinbelow with reference to Table Table1.

[3785] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM266 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3786]

[3787] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 267 (GAM267) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3788] GAM267 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM267 was detected is described hereinabove with reference to Figs. 2-8.

[3789] GAM267 gene, herein designated GAM GENE, and GAM267 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3790] GAM267 gene, herein designated GAM GENE, encodes a GAM267 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM267 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM267 precursor RNA is designated SEQ ID:4007, and is provided hereinbelow with reference to the sequence listing part.

[3791] GAM267 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM267 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3792] An enzyme complex designated DICER COMPLEX, dices the GAM267 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM267 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM267 RNA is designated SEQ ID:4008, and is provided hereinbelow with reference to the sequence listing part.

[3793] GAM267 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM267 target RNA, herein designated GAM TARGET RNA. GAM267 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3794] GAM267 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM267 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM267 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM267 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM267 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3795] The complementary binding of GAM267 RNA, herein designated GAM RNA, to target binding sites on GAM267 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM267 target RNA, herein designated GAM TARGET RNA, into GAM267 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3796] It is appreciated that GAM267 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM267 target genes. The mRNA of each one of this plurality of GAM267 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM267 RNA, herein designated GAM RNA, and which when bound by GAM267 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM267 target proteins.

[3797] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM267 gene, herein designated GAM GENE, on one or more GAM267 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3798] It is yet further appreciated that specific functions, and accordingly utilities, of GAM267 correlate with, and may be deduced from, the identity of the target genes which GAM267 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3799] Nucleotide sequences of the GAM267 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM267 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM267 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM267 are further described hereinbelow with reference to Table Table1.

[3800] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM267 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3801]

[3802] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 268 (GAM268) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3803] GAM268 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM268 was detected is described hereinabove with reference to Figs. 2-8.

[3804] GAM268 gene, herein designated GAM GENE, and GAM268 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3805] GAM268 gene, herein designated GAM GENE, encodes a GAM268 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM268 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM268 precursor RNA is designated SEQ ID:4018, and is provided hereinbelow with reference to the sequence listing part.

[3806] GAM268 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM268 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3807] An enzyme complex designated DICER COMPLEX, dices the GAM268 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM268 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 75%) nucleotide sequence of GAM268 RNA is designated SEQ ID:4019, and is provided hereinbelow with reference to the sequence listing part.

[3808] GAM268 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM268 target RNA, herein designated GAM TARGET RNA. GAM268 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3809] GAM268 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM268 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM268 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM268 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM268 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3810] The complementary binding of GAM268 RNA, herein designated GAM RNA, to target binding sites on GAM268 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM268 target RNA, herein designated GAM TARGET RNA, into GAM268 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3811] It is appreciated that GAM268 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM268 target genes. The mRNA of each one of this plurality of GAM268 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM268 RNA,

herein designated GAM RNA, and which when bound by GAM268 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM268 target proteins.

[3812] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM268 gene, herein designated GAM GENE, on one or more GAM268 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3813] It is yet further appreciated that specific functions, and accordingly utilities, of GAM268 correlate with, and may be deduced from, the identity of the target genes which

GAM268 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3814] Nucleotide sequences of the GAM268 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM268 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM268 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM268 are further described hereinbelow with reference to Table Table1.

[3815] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM268 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3816]

[3817] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 269 (GAM269) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3818] GAM269 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM269 was detected is described hereinabove with reference to Figs. 2-8.

[3819] GAM269 gene, herein designated GAM GENE, and GAM269 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3820] GAM269 gene, herein designated GAM GENE, encodes a GAM269 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM269 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM269 precursor RNA is designated SEQ ID:4038, and is provided hereinbelow with reference to the sequence listing part.

[3821] GAM269 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM269 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[3822] An enzyme complex designated DICER COMPLEX, dices the GAM269 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM269 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 24%) nucleotide sequence of GAM269 RNA is designated SEQ ID:4039, and is provided hereinbelow with reference to the sequence listing part.

[3823] GAM269 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM269 target RNA, herein designated GAM TARGET RNA.
GAM269 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3824] GAM269 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM269 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM269 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM269 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM269 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3825] The complementary binding of GAM269 RNA, herein designated GAM RNA, to target binding sites on GAM269 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM269 target RNA, herein desig-

nated GAM TARGET RNA, into GAM269 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3826] It is appreciated that GAM269 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM269 target genes. The mRNA of each one of this plurality of GAM269 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM269 RNA, herein designated GAM RNA, and which when bound by GAM269 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM269 target proteins.

[3827] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM269 gene, herein designated GAM GENE, on one or more GAM269 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3828] It is yet further appreciated that specific functions, and accordingly utilities, of GAM269 correlate with, and may be deduced from, the identity of the target genes which GAM269 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3829] Nucleotide sequences of the GAM269 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM269 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM269 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM269 are further described hereinbelow with reference to Table Table1.

[3830] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM269 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[3831]

[3832] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 270 (GAM270) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3833] GAM270 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM270 was detected is described hereinabove with reference to Figs. 2-8.

[3834] GAM270 gene, herein designated GAM GENE, and GAM270 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3835] GAM270 gene, herein designated GAM GENE, encodes a GAM270 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM270 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM270 precursor RNA is designated SEQ ID:4052, and is provided hereinbelow with ref-

erence to the sequence listing part.

[3836] GAM270 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM270 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3837] An enzyme complex designated DICER COMPLEX, dices the GAM270 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM270 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM270 RNA is designated SEQ ID:4053, and is provided hereinbelow with reference to the sequence listing part.

[3838] GAM270 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM270 target RNA, herein designated GAM TARGET RNA.

GAM270 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3839] GAM270 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM270 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM270 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM270 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM270 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3840] The complementary binding of GAM270 RNA, herein designated GAM RNA, to target binding sites on GAM270 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM270 target RNA, herein designated GAM TARGET RNA, into GAM270 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3841] It is appreciated that GAM270 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM270 target genes. The mRNA of each one of this plurality of GAM270 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM270 RNA, herein designated GAM RNA, and which when bound by GAM270 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM270 target proteins.

[3842] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM270 gene, herein designated GAM GENE, on one or more GAM270 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3843] It is yet further appreciated that specific functions, and accordingly utilities, of GAM270 correlate with, and may be deduced from, the identity of the target genes which GAM270 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3844] Nucleotide sequences of the GAM270 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM270 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM270 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM270 are further described hereinbelow with reference to Table Table1.

[3845] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM270 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3846]

[3847] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 271 (GAM271) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3848] GAM271 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM271 was detected is described hereinabove with reference to Figs. 2-8.

[3849] GAM271 gene, herein designated GAM GENE, and GAM271 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[3850] GAM271 gene, herein designated GAM GENE, encodes a GAM271 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM271 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM271 precursor RNA is designated SEQ ID:4068, and is provided hereinbelow with reference to the sequence listing part.

[3851] GAM271 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM271 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3852] An enzyme complex designated DICER COMPLEX, dices the GAM271 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM271 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM271 RNA is designated SEQ ID:4069, and is provided hereinbelow with reference to the sequence listing part.

[3853] GAM271 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM271 target RNA, herein designated GAM TARGET RNA. GAM271 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3854] GAM271 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM271 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM271 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM271 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM271 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3855] The complementary binding of GAM271 RNA, herein designated GAM RNA, to target binding sites on GAM271 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM271 target RNA, herein designated GAM TARGET RNA, into GAM271 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3856] It is appreciated that GAM271 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM271 target genes. The mRNA of each one of this plurality of GAM271 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM271 RNA, herein designated GAM RNA, and which when bound by GAM271 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM271 target proteins.

[3857] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM271 gene, herein designated GAM GENE, on one or more GAM271 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[3858] It is yet further appreciated that specific functions, and accordingly utilities, of GAM271 correlate with, and may be deduced from, the identity of the target genes which GAM271 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3859] Nucleotide sequences of the GAM271 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM271 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM271 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM271 are further described hereinbelow with reference to Table Table1.

[3860] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM271 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3861]

[3862] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

272 (GAM272) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3863] GAM272 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM272 was detected is described hereinabove with reference to Figs. 2-8.

[3864] GAM272 gene, herein designated GAM GENE, and GAM272 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3865] GAM272 gene, herein designated GAM GENE, encodes a GAM272 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM272 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM272 precursor RNA is designated SEQ ID:4104, and is provided hereinbelow with reference to the sequence listing part.

[3866] GAM272 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM272 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3867] An enzyme complex designated DICER COMPLEX, dices the GAM272 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM272 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM272 RNA is designated SEQ ID:4105, and is provided hereinbelow with reference to the sequence listing part.

[3868] GAM272 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM272 target RNA, herein designated GAM TARGET RNA. GAM272 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3869] GAM272 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM272 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM272 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM272 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM272 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3870] The complementary binding of GAM272 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM272 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM272 target RNA, herein designated GAM TARGET RNA, into GAM272 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3871] It is appreciated that GAM272 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM272 target genes. The mRNA of each one of this plurality of GAM272 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM272 RNA, herein designated GAM RNA, and which when bound by GAM272 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM272 target proteins.

[3872] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM272 gene, herein designated GAM GENE, on one or more GAM272 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3873] It is yet further appreciated that specific functions, and accordingly utilities, of GAM272 correlate with, and may be deduced from, the identity of the target genes which GAM272 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3874] Nucleotide sequences of the GAM272 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM272 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM272 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM272 are further described hereinbelow with reference to Table Table1.

[3875] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM272 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3876]

[3877] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 273 (GAM273) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3878] GAM273 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM273 was detected is described hereinabove with reference to Figs. 2-8.

[3879] GAM273 gene, herein designated GAM GENE, and GAM273 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3880] GAM273 gene, herein designated GAM GENE, encodes a GAM273 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM273 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM273 precursor RNA is designated SEQ ID:4125, and is provided hereinbelow with reference to the sequence listing part.

[3881] GAM273 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM273 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3882] An enzyme complex designated DICER COMPLEX, dices the GAM273 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM273 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 54%) nucleotide sequence of GAM273 RNA is designated SEQ ID:4126, and is provided hereinbelow with reference to the sequence listing part.

[3883] GAM273 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM273 target RNA, herein designated GAM TARGET RNA. GAM273 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3884] GAM273 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM273 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM273 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM273 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM273 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3885] The complementary binding of GAM273 RNA, herein designated GAM RNA, to target binding sites on GAM273 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM273 target RNA, herein designated GAM TARGET RNA, into GAM273 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3886] It is appreciated that GAM273 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM273 target genes. The mRNA of each one of this plurality of GAM273 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM273 RNA, herein designated GAM RNA, and which when bound by

GAM273 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM273 target proteins.

[3887] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM273 gene, herein designated GAM GENE, on one or more GAM273 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3888] It is yet further appreciated that specific functions, and accordingly utilities, of GAM273 correlate with, and may be deduced from, the identity of the target genes which GAM273 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[3889] Nucleotide sequences of the GAM273 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM273 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM273 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM273 are further described hereinbelow with reference to Table Table1.

[3890] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM273 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3891]

[3892] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 274 (GAM274) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3893] GAM274 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM274 was detected is described hereinabove with reference to Figs. 2-8.

[3894] GAM274 gene, herein designated GAM GENE, and GAM274 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3895] GAM274 gene, herein designated GAM GENE, encodes a GAM274 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM274 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM274 precursor RNA is designated SEQ ID:4137, and is provided hereinbelow with reference to the sequence listing part.

[3896] GAM274 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM274 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[3897] An enzyme complex designated DICER COMPLEX, dices the GAM274 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM274 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM274 RNA is designated SEQ ID:4138, and is provided hereinbelow with reference to the sequence listing part.

[3898] GAM274 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM274 target RNA, herein designated GAM TARGET RNA. GAM274 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3899] GAM274 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM274 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM274 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM274 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM274 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3900] The complementary binding of GAM274 RNA, herein designated GAM RNA, to target binding sites on GAM274 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM274 target RNA, herein designated GAM TARGET RNA, into GAM274 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3901] It is appreciated that GAM274 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM274 target genes. The mRNA of each one of this plurality of GAM274 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM274 RNA, herein designated GAM RNA, and which when bound by GAM274 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM274 target proteins.

[3902] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM274 gene, herein designated GAM GENE, on one or more GAM274 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3903] It is yet further appreciated that specific functions, and accordingly utilities, of GAM274 correlate with, and may be deduced from, the identity of the target genes which GAM274 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3904] Nucleotide sequences of the GAM274 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM274 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM274 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM274 are further described hereinbelow with reference to Table Table1.

[3905] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM274 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3906]

[3907] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 275 (GAM275) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3908] GAM275 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM275 was detected is described hereinabove with reference to Figs. 2-8.

[3909] GAM275 gene, herein designated GAM GENE, and GAM275 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3910] GAM275 gene, herein designated GAM GENE, encodes a GAM275 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM275 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM275 precursor RNA is designated SEQ ID:4142, and is provided hereinbelow with reference to the sequence listing part.

[3911] GAM275 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM275 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3912] An enzyme complex designated DICER COMPLEX, dices the GAM275 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM275 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM275 RNA is designated SEQ ID:4143, and is provided hereinbelow with reference to the sequence listing part.

[3913] GAM275 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM275

target RNA, herein designated GAM TARGET RNA.

GAM275 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3914] GAM275 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM275 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM275 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM275 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM275 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3915] The complementary binding of GAM275 RNA, herein designated GAM RNA, to target binding sites on GAM275 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM275 target RNA, herein designated GAM TARGET RNA, into GAM275 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3916] It is appreciated that GAM275 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM275 target genes. The mRNA of each one of this plurality of GAM275 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM275 RNA, herein designated GAM RNA, and which when bound by GAM275 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM275 target proteins.

[3917] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM275 gene, herein designated GAM GENE, on one or more GAM275 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3918] It is yet further appreciated that specific functions, and accordingly utilities, of GAM275 correlate with, and may be deduced from, the identity of the target genes which GAM275 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3919] Nucleotide sequences of the GAM275 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM275 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM275 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM275 are further described hereinbelow with reference to Table Table1.

[3920] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM275 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3921]

[3922] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 276 (GAM276) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3923] GAM276 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM276 was detected is described hereinabove with reference to Figs. 2-8.

[3924] GAM276 gene, herein designated GAM GENE, and GAM276 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3925] GAM276 gene, herein designated GAM GENE, encodes a GAM276 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM276 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM276 precursor RNA is designated SEQ ID:4157, and is provided hereinbelow with reference to the sequence listing part.

[3926] GAM276 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM276 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3927] An enzyme complex designated DICER COMPLEX, dices the GAM276 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM276 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 44%) nucleotide sequence of GAM276 RNA is designated SEQ ID:4158, and is provided hereinbelow with reference to the sequence listing part.

[3928] GAM276 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM276 target RNA, herein designated GAM TARGET RNA. GAM276 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3929] GAM276 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM276 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM276 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM276 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM276 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3930] The complementary binding of GAM276 RNA, herein designated GAM RNA, to target binding sites on GAM276 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM276 target RNA, herein designated GAM TARGET RNA, into GAM276 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3931] It is appreciated that GAM276 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM276 target genes. The mRNA of each one of this plu-

rality of GAM276 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM276 RNA, herein designated GAM RNA, and which when bound by GAM276 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM276 target proteins.

[3932] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM276 gene, herein designated GAM GENE, on one or more GAM276 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3933] It is yet further appreciated that specific functions, and accordingly utilities, of GAM276 correlate with, and may be deduced from, the identity of the target genes which GAM276 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3934] Nucleotide sequences of the GAM276 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM276 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM276 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM276 are further described hereinbelow with reference to Table Table1.

[3935] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM276 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3936]

[3937] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 277 (GAM277) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[3938] GAM277 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM277 was detected is described hereinabove with reference to Figs. 2-8.

[3939] GAM277 gene, herein designated GAM GENE, and GAM277 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3940] GAM277 gene, herein designated GAM GENE, encodes a GAM277 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM277 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM277 precursor RNA is designated SEQ ID:4177, and is provided hereinbelow with reference to the sequence listing part.

[3941] GAM277 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM277 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3942] An enzyme complex designated DICER COMPLEX, dices the GAM277 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM277 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM277 RNA is designated SEQ ID:4178, and is provided hereinbelow with reference to the sequence listing part.

[3943] GAM277 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM277 target RNA, herein designated GAM TARGET RNA. GAM277 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[3944] GAM277 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM277 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM277 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM277 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM277 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3945] The complementary binding of GAM277 RNA, herein designated GAM RNA, to target binding sites on GAM277 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM277 target RNA, herein designated GAM TARGET RNA, into GAM277 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3946] It is appreciated that GAM277 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM277 target genes. The mRNA of each one of this plurality of GAM277 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM277 RNA, herein designated GAM RNA, and which when bound by GAM277 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM277 target proteins.

[3947] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM277 gene, herein designated GAM GENE, on one or more GAM277 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3948] It is yet further appreciated that specific functions, and accordingly utilities, of GAM277 correlate with, and may be deduced from, the identity of the target genes which GAM277 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3949] Nucleotide sequences of the GAM277 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM277 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM277 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM277 are further described hereinbelow with reference to Table Table1.

[3950] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM277 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3951]

[3952] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 278 (GAM278) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3953] GAM278 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM278 was detected is described hereinabove with reference to Figs. 2-8.

[3954] GAM278 gene, herein designated GAM GENE, and GAM278 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3955] GAM278 gene, herein designated GAM GENE, encodes a GAM278 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM278 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM278 precursor RNA is designated SEQ ID:4202, and is provided hereinbelow with reference to the sequence listing part.

[3956] GAM278 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM278 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3957] An enzyme complex designated DICER COMPLEX, dices the GAM278 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM278 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of

GAM278 RNA is designated SEQ ID:4203, and is provided hereinbelow with reference to the sequence listing part.

[3958] GAM278 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM278 target RNA, herein designated GAM TARGET RNA. GAM278 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3959] GAM278 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM278 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM278 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM278 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM278 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3960] The complementary binding of GAM278 RNA, herein designated GAM RNA, to target binding sites on GAM278 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM278 target RNA, herein designated GAM TARGET RNA, into GAM278 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3961] It is appreciated that GAM278 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM278 target genes. The mRNA of each one of this plurality of GAM278 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM278 RNA, herein designated GAM RNA, and which when bound by GAM278 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM278 target proteins.

[3962] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM278 gene, herein designated GAM GENE, on one or more GAM278 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3963] It is yet further appreciated that specific functions, and accordingly utilities, of GAM278 correlate with, and may be deduced from, the identity of the target genes which GAM278 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3964] Nucleotide sequences of the GAM278 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM278 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM278 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM278 are further described hereinbelow with reference to Table Table1.

[3965] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM278 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3966]

[3967] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 279 (GAM279) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3968] GAM279 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM279 was detected is described hereinabove

with reference to Figs. 2-8.

[3969] GAM279 gene, herein designated GAM GENE, and GAM279 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3970] GAM279 gene, herein designated GAM GENE, encodes a GAM279 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM279 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM279 precursor RNA is designated SEQ ID:4234, and is provided hereinbelow with reference to the sequence listing part.

[3971] GAM279 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM279 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3972] An enzyme complex designated DICER COMPLEX, dices the GAM279 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM279 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 84%) nucleotide sequence of GAM279 RNA is designated SEQ ID:4235, and is provided hereinbelow with reference to the sequence listing part.

[3973] GAM279 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM279 target RNA, herein designated GAM TARGET RNA. GAM279 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3974] GAM279 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM279 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM279 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM279 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM279 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3975] The complementary binding of GAM279 RNA, herein designated GAM RNA, to target binding sites on GAM279 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM279 target RNA, herein designated GAM TARGET RNA, into GAM279 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[3976] It is appreciated that GAM279 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM279 target genes. The mRNA of each one of this plurality of GAM279 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM279 RNA, herein designated GAM RNA, and which when bound by GAM279 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM279 target proteins.

[3977] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM279 gene, herein designated GAM GENE, on one or more GAM279 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3978] It is yet further appreciated that specific functions, and accordingly utilities, of GAM279 correlate with, and may be deduced from, the identity of the target genes which GAM279 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3979] Nucleotide sequences of the GAM279 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM279 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM279 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM279 are further described hereinbelow with reference to Table Table1.

[3980] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM279 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3981]

[3982] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 280 (GAM280) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3983] GAM280 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM280 was detected is described hereinabove with reference to Figs. 2-8.

[3984] GAM280 gene, herein designated GAM GENE, and GAM280 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[3985] GAM280 gene, herein designated GAM GENE, encodes a GAM280 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM280 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM280 precursor RNA is designated SEQ ID:4245, and is provided hereinbelow with reference to the sequence listing part.

[3986] GAM280 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM280 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[3987] An enzyme complex designated DICER COMPLEX, dices the GAM280 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM280 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM280 RNA is designated SEQ ID:4246, and is provided hereinbelow with reference to the sequence listing part.

[3988] GAM280 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM280 target RNA, herein designated GAM TARGET RNA.

GAM280 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[3989] GAM280 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM280 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM280 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM280 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM280 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[3990] The complementary binding of GAM280 RNA, herein designated GAM RNA, to target binding sites on GAM280 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM280 target RNA, herein designated GAM TARGET RNA, into GAM280 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[3991] It is appreciated that GAM280 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM280 target genes. The mRNA of each one of this plurality of GAM280 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM280 RNA, herein designated GAM RNA, and which when bound by GAM280 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM280 target proteins.

[3992] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM280 gene, herein designated GAM GENE, on one or more GAM280 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[3993] It is yet further appreciated that specific functions, and accordingly utilities, of GAM280 correlate with, and may be deduced from, the identity of the target genes which GAM280 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[3994] Nucleotide sequences of the GAM280 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM280 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM280 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM280 are further described hereinbelow with reference to Table Table1.

[3995] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM280 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[3996]

[3997] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 281 (GAM281) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[3998] GAM281 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM281 was detected is described hereinabove with reference to Figs. 2-8.

[3999] GAM281 gene, herein designated GAM GENE, and GAM281 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4000] GAM281 gene, herein designated GAM GENE, encodes a

GAM281 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM281 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM281 precursor RNA is designated SEQ ID:4261, and is provided hereinbelow with reference to the sequence listing part.

[4001] GAM281 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM281 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4002] An enzyme complex designated DICER COMPLEX, dices the GAM281 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM281 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 22%) nucleotide sequence of GAM281 RNA is designated SEQ ID:4262, and is provided hereinbelow with reference to the sequence listing part.

[4003] GAM281 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM281 target RNA, herein designated GAM TARGET RNA. GAM281 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4004] GAM281 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM281 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM281 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM281 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM281 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4005] The complementary binding of GAM281 RNA, herein designated GAM RNA, to target binding sites on GAM281 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM281 target RNA, herein designated GAM TARGET RNA, into GAM281 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4006] It is appreciated that GAM281 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM281 target genes. The mRNA of each one of this plurality of GAM281 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM281 RNA, herein designated GAM RNA, and which when bound by GAM281 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM281 target proteins.

[4007] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM281 gene, herein designated GAM GENE, on one or more GAM281 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4008] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM281 correlate with, and may be deduced from, the identity of the target genes which GAM281 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4009] Nucleotide sequences of the GAM281 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM281 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM281 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM281 are further described hereinbelow with reference to Table Table1.

[4010] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM281 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4011]

[4012] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 282 (GAM282) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[4013] GAM282 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM282 was detected is described hereinabove with reference to Figs. 2-8.

[4014] GAM282 gene, herein designated GAM GENE, and GAM282 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4015] GAM282 gene, herein designated GAM GENE, encodes a GAM282 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM282 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM282 precursor RNA is designated SEQ ID:4276, and is provided hereinbelow with reference to the sequence listing part.

[4016] GAM282 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM282 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4017] An enzyme complex designated DICER COMPLEX, dices the GAM282 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM282 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM282 RNA is designated SEQ ID:4277, and is provided hereinbelow with reference to the sequence listing part.

[4018] GAM282 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM282 target RNA, herein designated GAM TARGET RNA. GAM282 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4019] GAM282 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM282 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM282 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM282 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM282 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4020] The complementary binding of GAM282 RNA, herein designated GAM RNA, to target binding sites on GAM282 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM282 target RNA, herein designated GAM TARGET RNA, into GAM282 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4021] It is appreciated that GAM282 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM282 target genes. The mRNA of each one of this plurality of GAM282 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM282 RNA, herein designated GAM RNA, and which when bound by GAM282 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM282 target proteins.

[4022] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM282 gene, herein designated GAM GENE, on one or more GAM282 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4023] It is yet further appreciated that specific functions, and accordingly utilities, of GAM282 correlate with, and may be deduced from, the identity of the target genes which GAM282 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4024] Nucleotide sequences of the GAM282 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM282 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM282 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM282 are further described hereinbelow with reference to Table Table1.

[4025] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM282 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4026]

[4027] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 283 (GAM283) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4028] GAM283 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM283 was detected is described hereinabove with reference to Figs. 2-8.

[4029] GAM283 gene, herein designated GAM GENE, and GAM283 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4030] GAM283 gene, herein designated GAM GENE, encodes a GAM283 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM283 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM283 precursor RNA is designated SEQ ID:4290, and is provided hereinbelow with reference to the sequence listing part.

[4031] GAM283 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM283 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4032] An enzyme complex designated DICER COMPLEX, dices the GAM283 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM283 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM283 RNA is designated SEQ ID:4291, and is provided

hereinbelow with reference to the sequence listing part.

[4033] GAM283 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM283 target RNA, herein designated GAM TARGET RNA.

GAM283 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4034] GAM283 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM283 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM283 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM283 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM283 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4035] The complementary binding of GAM283 RNA, herein designated GAM RNA, to target binding sites on GAM283 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM283 target RNA, herein designated GAM TARGET RNA, into GAM283 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4036] It is appreciated that GAM283 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM283 target genes. The mRNA of each one of this plurality of GAM283 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM283 RNA, herein designated GAM RNA, and which when bound by GAM283 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM283 tar-

get proteins.

[4037] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM283 gene, herein designated GAM GENE, on one or more GAM283 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4038] It is yet further appreciated that specific functions, and accordingly utilities, of GAM283 correlate with, and may be deduced from, the identity of the target genes which GAM283 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4039] Nucleotide sequences of the GAM283 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM283 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM283 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM283 are further described hereinbelow with reference to Table Table1.

[4040] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM283 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4041]

[4042] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 284 (GAM284) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4043] GAM284 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM284 was detected is described hereinabove with reference to Figs. 2-8.

[4044] GAM284 gene, herein designated GAM GENE, and GAM284 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4045] GAM284 gene, herein designated GAM GENE, encodes a GAM284 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM284 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM284 precursor RNA is designated SEQ ID:4301, and is provided hereinbelow with reference to the sequence listing part.

[4046] GAM284 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM284 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4047] An enzyme complex designated DICER COMPLEX, dices

the GAM284 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM284 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM284 RNA is designated SEQ ID:4302, and is provided hereinbelow with reference to the sequence listing part.

[4048] GAM284 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM284 target RNA, herein designated GAM TARGET RNA. GAM284 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4049] GAM284 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM284 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM284

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM284 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM284 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4050] The complementary binding of GAM284 RNA, herein designated GAM RNA, to target binding sites on GAM284 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM284 target RNA, herein designated GAM TARGET RNA, into GAM284 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4051] It is appreciated that GAM284 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM284 target genes. The mRNA of each one of this plurality of GAM284 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM284 RNA, herein designated GAM RNA, and which when bound by GAM284 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM284 target proteins.

[4052] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM284 gene, herein designated GAM GENE, on one or more GAM284 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4053] It is yet further appreciated that specific functions, and accordingly utilities, of GAM284 correlate with, and may be deduced from, the identity of the target genes which GAM284 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4054] Nucleotide sequences of the GAM284 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM284 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM284 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM284 are further described hereinbelow with reference to Table Table1.

[4055] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM284 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4056]

[4057] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 285 (GAM285) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4058] GAM285 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM285 was detected is described hereinabove with reference to Figs. 2-8.

[4059] GAM285 gene, herein designated GAM GENE, and GAM285 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4060] GAM285 gene, herein designated GAM GENE, encodes a GAM285 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM285 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM285 precursor RNA is designated SEQ ID:4318, and is provided hereinbelow with reference to the sequence listing part.

[4061] GAM285 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM285 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4062] An enzyme complex designated DICER COMPLEX, dices the GAM285 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM285 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 43%) nucleotide sequence of GAM285 RNA is designated SEQ ID:4319, and is provided hereinbelow with reference to the sequence listing part.

[4063] GAM285 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM285 target RNA, herein designated GAM TARGET RNA. GAM285 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4064] GAM285 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM285 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM285 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM285 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM285 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[4065] The complementary binding of GAM285 RNA, herein designated GAM RNA, to target binding sites on GAM285 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM285 target RNA, herein designated GAM TARGET RNA, into GAM285 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4066] It is appreciated that GAM285 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM285 target genes. The mRNA of each one of this plurality of GAM285 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM285 RNA, herein designated GAM RNA, and which when bound by GAM285 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM285 target proteins.

[4067] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM285 gene, herein designated GAM GENE, on one or

more GAM285 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4068] It is yet further appreciated that specific functions, and accordingly utilities, of GAM285 correlate with, and may be deduced from, the identity of the target genes which GAM285 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4069] Nucleotide sequences of the GAM285 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM285 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM285 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM285 are further de-

scribed hereinbelow with reference to Table Table1.

[4070] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM285 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4071]

[4072] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 286 (GAM286) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4073] GAM286 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM286 was detected is described hereinabove with reference to Figs. 2-8.

[4074] GAM286 gene, herein designated GAM GENE, and GAM286 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4075] GAM286 gene, herein designated GAM GENE, encodes a GAM286 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM286 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM286 precursor RNA is designated SEQ ID:4328, and is provided hereinbelow with reference to the sequence listing part.

[4076] GAM286 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM286 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4077] An enzyme complex designated DICER COMPLEX, dices the GAM286 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM286 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM286 RNA is designated SEQ ID:4329, and is provided hereinbelow with reference to the sequence listing part.

[4078] GAM286 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM286 target RNA, herein designated GAM TARGET RNA. GAM286 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4079] GAM286 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM286 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM286 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM286 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM286 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4080] The complementary binding of GAM286 RNA, herein designated GAM RNA, to target binding sites on GAM286 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM286 target RNA, herein designated GAM TARGET RNA, into GAM286 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4081] It is appreciated that GAM286 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM286 target genes. The mRNA of each one of this plurality of GAM286 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM286 RNA, herein designated GAM RNA, and which when bound by GAM286 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM286 target proteins.

[4082] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM286 gene, herein designated GAM GENE, on one or more GAM286 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4083] It is yet further appreciated that specific functions, and accordingly utilities, of GAM286 correlate with, and may

be deduced from, the identity of the target genes which GAM286 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4084] Nucleotide sequences of the GAM286 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM286 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM286 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM286 are further described hereinbelow with reference to Table Table1.

[4085] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM286 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4086]

[4087] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 287 (GAM287) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4088] GAM287 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM287 was detected is described hereinabove with reference to Figs. 2-8.

[4089] GAM287 gene, herein designated GAM GENE, and GAM287 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4090] GAM287 gene, herein designated GAM GENE, encodes a GAM287 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM287 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM287 precursor RNA is designated SEQ ID:4344, and is provided hereinbelow with reference to the sequence listing part.

[4091] GAM287 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM287 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4092] An enzyme complex designated DICER COMPLEX, dices the GAM287 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM287 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 30%) nucleotide sequence of GAM287 RNA is designated SEQ ID:4345, and is provided hereinbelow with reference to the sequence listing part.

[4093] GAM287 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM287 target RNA, herein designated GAM TARGET RNA. GAM287 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4094] GAM287 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM287 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM287 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM287 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM287 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4095] The complementary binding of GAM287 RNA, herein designated GAM RNA, to target binding sites on GAM287 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM287 target RNA, herein designated GAM TARGET RNA, into GAM287 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[4096] It is appreciated that GAM287 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM287 target genes. The mRNA of each one of this plurality of GAM287 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM287 RNA, herein designated GAM RNA, and which when bound by GAM287 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM287 target proteins.

[4097] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM287 gene, herein designated GAM GENE, on one or more GAM287 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4098] It is yet further appreciated that specific functions, and accordingly utilities, of GAM287 correlate with, and may be deduced from, the identity of the target genes which GAM287 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4099] Nucleotide sequences of the GAM287 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM287 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM287 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM287 are further described hereinbelow with reference to Table Table1.

[4100] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM287 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4101]

[4102] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 288 (GAM288) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4103] GAM288 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM288 was detected is described hereinabove with reference to Figs. 2-8.

[4104] GAM288 gene, herein designated GAM GENE, and GAM288 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4105] GAM288 gene, herein designated GAM GENE, encodes a GAM288 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM288 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM288 precursor RNA is designated SEQ ID:4353, and is provided hereinbelow with reference to the sequence listing part.

[4106] GAM288 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM288 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4107] An enzyme complex designated DICER COMPLEX, dices the GAM288 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM288 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 73%) nucleotide sequence of GAM288 RNA is designated SEQ ID:4354, and is provided hereinbelow with reference to the sequence listing part.

[4108] GAM288 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM288 target RNA, herein designated GAM TARGET RNA.

GAM288 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4109] GAM288 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM288 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM288 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM288 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM288 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4110] The complementary binding of GAM288 RNA, herein designated GAM RNA, to target binding sites on GAM288 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM288 target RNA, herein designated GAM TARGET RNA, into GAM288 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4111] It is appreciated that GAM288 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM288 target genes. The mRNA of each one of this plurality of GAM288 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM288 RNA, herein designated GAM RNA, and which when bound by GAM288 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM288 target proteins.

[4112] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM288 gene, herein designated GAM GENE, on one or more GAM288 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4113] It is yet further appreciated that specific functions, and accordingly utilities, of GAM288 correlate with, and may be deduced from, the identity of the target genes which GAM288 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4114] Nucleotide sequences of the GAM288 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM288 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM288 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM288 are further described hereinbelow with reference to Table Table1.

[4115] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM288 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4116]

[4117] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 289 (GAM289) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4118] GAM289 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM289 was detected is described hereinabove with reference to Figs. 2-8.

[4119] GAM289 gene, herein designated GAM GENE, and GAM289 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4120] GAM289 gene, herein designated GAM GENE, encodes a

GAM289 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM289 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM289 precursor RNA is designated SEQ ID:4369, and is provided hereinbelow with reference to the sequence listing part.

[4121] GAM289 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM289 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4122] An enzyme complex designated DICER COMPLEX, dices the GAM289 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM289 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM289 RNA is designated SEQ ID:4370, and is provided hereinbelow with reference to the sequence listing part.

[4123] GAM289 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM289 target RNA, herein designated GAM TARGET RNA. GAM289 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4124] GAM289 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM289 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM289 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM289 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM289 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4125] The complementary binding of GAM289 RNA, herein designated GAM RNA, to target binding sites on GAM289 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM289 target RNA, herein designated GAM TARGET RNA, into GAM289 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4126] It is appreciated that GAM289 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM289 target genes. The mRNA of each one of this plurality of GAM289 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM289 RNA, herein designated GAM RNA, and which when bound by GAM289 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM289 target proteins.

[4127] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM289 gene, herein designated GAM GENE, on one or more GAM289 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4128] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM289 correlate with, and may be deduced from, the identity of the target genes which GAM289 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4129] Nucleotide sequences of the GAM289 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM289 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM289 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM289 are further described hereinbelow with reference to Table Table1.

[4130] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM289 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4131]

[4132] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 290 (GAM290) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[4133] GAM290 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM290 was detected is described hereinabove with reference to Figs. 2-8.

[4134] GAM290 gene, herein designated GAM GENE, and GAM290 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4135] GAM290 gene, herein designated GAM GENE, encodes a GAM290 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM290 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM290 precursor RNA is designated SEQ ID:4378, and is provided hereinbelow with reference to the sequence listing part.

[4136] GAM290 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM290 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4137] An enzyme complex designated DICER COMPLEX, dices the GAM290 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM290 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 45%) nucleotide sequence of GAM290 RNA is designated SEQ ID:4379, and is provided hereinbelow with reference to the sequence listing part.

[4138] GAM290 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM290 target RNA, herein designated GAM TARGET RNA.
GAM290 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4139] GAM290 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM290 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM290 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM290 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM290 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4140] The complementary binding of GAM290 RNA, herein designated GAM RNA, to target binding sites on GAM290 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM290 target RNA, herein designated GAM TARGET RNA, into GAM290 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4141] It is appreciated that GAM290 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM290 target genes. The mRNA of each one of this plurality of GAM290 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM290 RNA, herein designated GAM RNA, and which when bound by GAM290 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM290 target proteins.

[4142] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM290 gene, herein designated GAM GENE, on one or more GAM290 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4143] It is yet further appreciated that specific functions, and accordingly utilities, of GAM290 correlate with, and may be deduced from, the identity of the target genes which GAM290 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4144] Nucleotide sequences of the GAM290 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM290 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM290 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM290 are further described hereinbelow with reference to Table Table1.

[4145] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM290 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4146]

[4147] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 291 (GAM291) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4148] GAM291 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM291 was detected is described hereinabove with reference to Figs. 2-8.

[4149] GAM291 gene, herein designated GAM GENE, and GAM291 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4150] GAM291 gene, herein designated GAM GENE, encodes a GAM291 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM291 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM291 precursor RNA is designated SEQ ID:4400, and is provided hereinbelow with reference to the sequence listing part.

[4151] GAM291 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM291 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4152] An enzyme complex designated DICER COMPLEX, dices the GAM291 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM291 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 45%) nucleotide sequence of GAM291 RNA is designated SEQ ID:4401, and is provided

hereinbelow with reference to the sequence listing part.

[4153] GAM291 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM291 target RNA, herein designated GAM TARGET RNA. GAM291 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4154] GAM291 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM291 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM291 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM291 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM291 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4155] The complementary binding of GAM291 RNA, herein designated GAM RNA, to target binding sites on GAM291 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM291 target RNA, herein designated GAM TARGET RNA, into GAM291 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4156] It is appreciated that GAM291 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM291 target genes. The mRNA of each one of this plurality of GAM291 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM291 RNA, herein designated GAM RNA, and which when bound by GAM291 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM291 tar-

get proteins.

[4157] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM291 gene, herein designated GAM GENE, on one or more GAM291 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4158] It is yet further appreciated that specific functions, and accordingly utilities, of GAM291 correlate with, and may be deduced from, the identity of the target genes which GAM291 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4159] Nucleotide sequences of the GAM291 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM291 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM291 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM291 are further described hereinbelow with reference to Table Table1.

[4160] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM291 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4161]

[4162] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 292 (GAM292) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4163] GAM292 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM292 was detected is described hereinabove with reference to Figs. 2-8.

[4164] GAM292 gene, herein designated GAM GENE, and GAM292 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4165] GAM292 gene, herein designated GAM GENE, encodes a GAM292 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM292 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM292 precursor RNA is designated SEQ ID:4429, and is provided hereinbelow with reference to the sequence listing part.

[4166] GAM292 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM292 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4167] An enzyme complex designated DICER COMPLEX, dices

the GAM292 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM292 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM292 RNA is designated SEQ ID:4430, and is provided hereinbelow with reference to the sequence listing part.

[4168] GAM292 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM292 target RNA, herein designated GAM TARGET RNA. GAM292 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4169] GAM292 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM292 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM292

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM292 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM292 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4170] The complementary binding of GAM292 RNA, herein designated GAM RNA, to target binding sites on GAM292 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM292 target RNA, herein designated GAM TARGET RNA, into GAM292 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4171] It is appreciated that GAM292 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM292 target genes. The mRNA of each one of this plurality of GAM292 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM292 RNA, herein designated GAM RNA, and which when bound by GAM292 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM292 target proteins.

[4172] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM292 gene, herein designated GAM GENE, on one or more GAM292 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4173] It is yet further appreciated that specific functions, and accordingly utilities, of GAM292 correlate with, and may be deduced from, the identity of the target genes which GAM292 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4174] Nucleotide sequences of the GAM292 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM292 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM292 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM292 are further described hereinbelow with reference to Table Table1.

[4175] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM292 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4176]

[4177] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 293 (GAM293) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4178] GAM293 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM293 was detected is described hereinabove with reference to Figs. 2-8.

[4179] GAM293 gene, herein designated GAM GENE, and GAM293 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4180] GAM293 gene, herein designated GAM GENE, encodes a GAM293 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM293 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM293 precursor RNA is designated SEQ ID:4449, and is provided hereinbelow with reference to the sequence listing part.

[4181] GAM293 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM293 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4182] An enzyme complex designated DICER COMPLEX, dices the GAM293 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM293 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM293 RNA is designated SEQ ID:4450, and is provided hereinbelow with reference to the sequence listing part.

[4183] GAM293 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM293 target RNA, herein designated GAM TARGET RNA. GAM293 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4184] GAM293 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM293 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM293 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM293 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM293 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[4185] The complementary binding of GAM293 RNA, herein designated GAM RNA, to target binding sites on GAM293 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM293 target RNA, herein designated GAM TARGET RNA, into GAM293 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4186] It is appreciated that GAM293 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM293 target genes. The mRNA of each one of this plurality of GAM293 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM293 RNA, herein designated GAM RNA, and which when bound by GAM293 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM293 target proteins.

[4187] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM293 gene, herein designated GAM GENE, on one or

more GAM293 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4188] It is yet further appreciated that specific functions, and accordingly utilities, of GAM293 correlate with, and may be deduced from, the identity of the target genes which GAM293 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4189] Nucleotide sequences of the GAM293 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM293 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM293 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM293 are further de-

scribed hereinbelow with reference to Table Table1.

[4190] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM293 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4191]

[4192] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 294 (GAM294) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4193] GAM294 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM294 was detected is described hereinabove with reference to Figs. 2-8.

[4194] GAM294 gene, herein designated GAM GENE, and GAM294 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4195] GAM294 gene, herein designated GAM GENE, encodes a GAM294 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM294 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM294 precursor RNA is designated SEQ ID:4458, and is provided hereinbelow with reference to the sequence listing part.

[4196] GAM294 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM294 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4197] An enzyme complex designated DICER COMPLEX, dices the GAM294 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM294 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM294 RNA is designated SEQ ID:4459, and is provided hereinbelow with reference to the sequence listing part.

[4198] GAM294 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM294 target RNA, herein designated GAM TARGET RNA. GAM294 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4199] GAM294 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM294 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM294 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM294 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM294 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4200] The complementary binding of GAM294 RNA, herein designated GAM RNA, to target binding sites on GAM294 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM294 target RNA, herein designated GAM TARGET RNA, into GAM294 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4201] It is appreciated that GAM294 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM294 target genes. The mRNA of each one of this plurality of GAM294 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM294 RNA, herein designated GAM RNA, and which when bound by GAM294 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM294 target proteins.

[4202] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM294 gene, herein designated GAM GENE, on one or more GAM294 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4203] It is yet further appreciated that specific functions, and accordingly utilities, of GAM294 correlate with, and may

be deduced from, the identity of the target genes which GAM294 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4204] Nucleotide sequences of the GAM294 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM294 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM294 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM294 are further described hereinbelow with reference to Table Table1.

[4205] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM294 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4206]

[4207] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 295 (GAM295) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4208] GAM295 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM295 was detected is described hereinabove with reference to Figs. 2-8.

[4209] GAM295 gene, herein designated GAM GENE, and GAM295 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4210] GAM295 gene, herein designated GAM GENE, encodes a GAM295 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM295 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM295 precursor RNA is designated SEQ ID:4462, and is provided hereinbelow with reference to the sequence listing part.

[4211] GAM295 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM295 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4212] An enzyme complex designated DICER COMPLEX, dices the GAM295 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM295 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM295 RNA is designated SEQ ID:4463, and is provided hereinbelow with reference to the sequence listing part.

[4213] GAM295 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM295 target RNA, herein designated GAM TARGET RNA. GAM295 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4214] GAM295 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM295 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM295 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM295 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM295 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4215] The complementary binding of GAM295 RNA, herein designated GAM RNA, to target binding sites on GAM295 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM295 target RNA, herein designated GAM TARGET RNA, into GAM295 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4216] It is appreciated that GAM295 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM295 target genes. The mRNA of each one of this plurality of GAM295 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM295 RNA, herein designated GAM RNA, and which when bound by GAM295 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM295 target proteins.

[4217] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM295 gene, herein designated GAM GENE, on one or more GAM295 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4218] It is yet further appreciated that specific functions, and accordingly utilities, of GAM295 correlate with, and may be deduced from, the identity of the target genes which GAM295 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4219] Nucleotide sequences of the GAM295 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM295 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM295 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM295 are further described hereinbelow with reference to Table Table1.

[4220] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM295 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4221]

[4222] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 296 (GAM296) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4223] GAM296 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM296 was detected is described hereinabove with reference to Figs. 2-8.

[4224] GAM296 gene, herein designated GAM GENE, and GAM296 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4225] GAM296 gene, herein designated GAM GENE, encodes a GAM296 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM296 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM296 precursor RNA is desig-

nated SEQ ID:4473, and is provided hereinbelow with reference to the sequence listing part.

[4226] GAM296 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM296 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4227] An enzyme complex designated DICER COMPLEX, dices the GAM296 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM296 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 36%) nucleotide sequence of GAM296 RNA is designated SEQ ID:4474, and is provided hereinbelow with reference to the sequence listing part.

[4228] GAM296 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM296 target RNA, herein designated GAM TARGET RNA. GAM296 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4229] GAM296 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM296 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM296 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM296 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM296

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4230] The complementary binding of GAM296 RNA, herein designated GAM RNA, to target binding sites on GAM296 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM296 target RNA, herein designated GAM TARGET RNA, into GAM296 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4231] It is appreciated that GAM296 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM296 target genes. The mRNA of each one of this plurality of GAM296 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM296 RNA, herein designated GAM RNA, and which when bound by GAM296 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM296 target proteins.

[4232] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM296 gene, herein designated GAM GENE, on one or more GAM296 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4233] It is yet further appreciated that specific functions, and accordingly utilities, of GAM296 correlate with, and may be deduced from, the identity of the target genes which GAM296 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4234] Nucleotide sequences of the GAM296 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM296 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM296 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM296 are further described hereinbelow with reference to Table Table1.

[4235] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM296 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4236]

[4237] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 297 (GAM297) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4238] GAM297 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM297 was detected is described hereinabove with reference to Figs. 2-8.

[4239] GAM297 gene, herein designated GAM GENE, and

GAM297 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4240] GAM297 gene, herein designated GAM GENE, encodes a GAM297 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM297 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM297 precursor RNA is designated SEQ ID:4488, and is provided hereinbelow with reference to the sequence listing part.

[4241] GAM297 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM297 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4242] An enzyme complex designated DICER COMPLEX, dices the GAM297 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM297 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 29%) nucleotide sequence of GAM297 RNA is designated SEQ ID:4489, and is provided hereinbelow with reference to the sequence listing part.

[4243] GAM297 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM297 target RNA, herein designated GAM TARGET RNA. GAM297 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4244] GAM297 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM297 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM297 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM297 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM297 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4245] The complementary binding of GAM297 RNA, herein designated GAM RNA, to target binding sites on GAM297 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM297 target RNA, herein designated GAM TARGET RNA, into GAM297 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4246] It is appreciated that GAM297 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM297 target genes. The mRNA of each one of this plurality of GAM297 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM297 RNA, herein designated GAM RNA, and which when bound by GAM297 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM297 target proteins.

[4247] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM297 gene, herein designated GAM GENE, on one or more GAM297 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4248] It is yet further appreciated that specific functions, and accordingly utilities, of GAM297 correlate with, and may be deduced from, the identity of the target genes which GAM297 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4249] Nucleotide sequences of the GAM297 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM297 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM297 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM297 are further described hereinbelow with reference to Table Table1.

[4250] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM297 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4251]

[4252] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 298 (GAM298) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4253] GAM298 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM298 was detected is described hereinabove with reference to Figs. 2-8.

[4254] GAM298 gene, herein designated GAM GENE, and GAM298 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4255] GAM298 gene, herein designated GAM GENE, encodes a GAM298 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM298 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM298 precursor RNA is designated SEQ ID:4508, and is provided hereinbelow with reference to the sequence listing part.

[4256] GAM298 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM298 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4257] An enzyme complex designated DICER COMPLEX, dices the GAM298 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM298 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM298 RNA is designated SEQ ID:4509, and is provided hereinbelow with reference to the sequence listing part.

[4258] GAM298 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM298 target RNA, herein designated GAM TARGET RNA. GAM298 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4259] GAM298 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM298 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM298 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM298 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM298 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4260] The complementary binding of GAM298 RNA, herein designated GAM RNA, to target binding sites on GAM298 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM298 target RNA, herein designated GAM TARGET RNA, into GAM298 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4261] It is appreciated that GAM298 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM298 target genes. The mRNA of each one of this plurality of GAM298 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM298 RNA, herein designated GAM RNA, and which when bound by GAM298 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM298 target proteins.

[4262] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM298 gene, herein designated GAM GENE, on one or more GAM298 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4263] It is yet further appreciated that specific functions, and accordingly utilities, of GAM298 correlate with, and may be deduced from, the identity of the target genes which GAM298 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4264] Nucleotide sequences of the GAM298 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM298 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM298 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM298 are further described hereinbelow with reference to Table Table1.

[4265] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM298 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4266]

[4267] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 299 (GAM299) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4268] GAM299 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM299 was detected is described hereinabove with reference to Figs. 2-8.

[4269] GAM299 gene, herein designated GAM GENE, and GAM299 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4270] GAM299 gene, herein designated GAM GENE, encodes a GAM299 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM299 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM299 precursor RNA is designated SEQ ID:4521, and is provided hereinbelow with reference to the sequence listing part.

[4271] GAM299 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM299 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4272] An enzyme complex designated DICER COMPLEX, dices the GAM299 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM299 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM299 RNA is designated SEQ ID:4522, and is provided hereinbelow with reference to the sequence listing part.

[4273] GAM299 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM299 target RNA, herein designated GAM TARGET RNA. GAM299 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4274] GAM299 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM299 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM299 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM299 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM299 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4275] The complementary binding of GAM299 RNA, herein designated GAM RNA, to target binding sites on GAM299 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM299 target RNA, herein designated GAM TARGET RNA, into GAM299 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4276] It is appreciated that GAM299 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM299 target genes. The mRNA of each one of this plurality of GAM299 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM299 RNA,

herein designated GAM RNA, and which when bound by GAM299 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM299 target proteins.

[4277] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM299 gene, herein designated GAM GENE, on one or more GAM299 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4278] It is yet further appreciated that specific functions, and accordingly utilities, of GAM299 correlate with, and may be deduced from, the identity of the target genes which

GAM299 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4279] Nucleotide sequences of the GAM299 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM299 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM299 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM299 are further described hereinbelow with reference to Table Table1.

[4280] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM299 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4281]

[4282] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 300 (GAM300) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4283] GAM300 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM300 was detected is described hereinabove with reference to Figs. 2-8.

[4284] GAM300 gene, herein designated GAM GENE, and GAM300 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4285] GAM300 gene, herein designated GAM GENE, encodes a GAM300 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM300 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM300 precursor RNA is designated SEQ ID:4544, and is provided hereinbelow with reference to the sequence listing part.

[4286] GAM300 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM300 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[4287] An enzyme complex designated DICER COMPLEX, dices the GAM300 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM300 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 20%) nucleotide sequence of GAM300 RNA is designated SEQ ID:4545, and is provided hereinbelow with reference to the sequence listing part.

[4288] GAM300 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM300 target RNA, herein designated GAM TARGET RNA.
GAM300 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4289] GAM300 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM300 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM300 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM300 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM300 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4290] The complementary binding of GAM300 RNA, herein designated GAM RNA, to target binding sites on GAM300 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM300 target RNA, herein desig-

nated GAM TARGET RNA, into GAM300 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4291] It is appreciated that GAM300 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM300 target genes. The mRNA of each one of this plurality of GAM300 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM300 RNA, herein designated GAM RNA, and which when bound by GAM300 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM300 target proteins.

[4292] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM300 gene, herein designated GAM GENE, on one or more GAM300 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4293] It is yet further appreciated that specific functions, and accordingly utilities, of GAM300 correlate with, and may be deduced from, the identity of the target genes which GAM300 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4294] Nucleotide sequences of the GAM300 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM300 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM300 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM300 are further described hereinbelow with reference to Table Table1.

[4295] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM300 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[4296]

[4297] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 301 (GAM301) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4298] GAM301 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM301 was detected is described hereinabove with reference to Figs. 2-8.

[4299] GAM301 gene, herein designated GAM GENE, and GAM301 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4300] GAM301 gene, herein designated GAM GENE, encodes a GAM301 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM301 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM301 precursor RNA is designated SEQ ID:4556, and is provided hereinbelow with ref-

erence to the sequence listing part.

[4301] GAM301 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM301 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4302] An enzyme complex designated DICER COMPLEX, dices the GAM301 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM301 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM301 RNA is designated SEQ ID:4557, and is provided hereinbelow with reference to the sequence listing part.

[4303] GAM301 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM301 target RNA, herein designated GAM TARGET RNA.

GAM301 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4304] GAM301 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM301 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM301 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM301 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM301 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4305] The complementary binding of GAM301 RNA, herein designated GAM RNA, to target binding sites on GAM301 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM301 target RNA, herein designated GAM TARGET RNA, into GAM301 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4306] It is appreciated that GAM301 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM301 target genes. The mRNA of each one of this plurality of GAM301 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM301 RNA, herein designated GAM RNA, and which when bound by GAM301 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM301 target proteins.

[4307] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM301 gene, herein designated GAM GENE, on one or more GAM301 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4308] It is yet further appreciated that specific functions, and accordingly utilities, of GAM301 correlate with, and may be deduced from, the identity of the target genes which GAM301 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4309] Nucleotide sequences of the GAM301 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM301 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM301 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM301 are further described hereinbelow with reference to Table Table1.

[4310] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM301 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4311]

[4312] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 302 (GAM302) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4313] GAM302 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM302 was detected is described hereinabove with reference to Figs. 2-8.

[4314] GAM302 gene, herein designated GAM GENE, and GAM302 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[4315] GAM302 gene, herein designated GAM GENE, encodes a GAM302 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM302 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM302 precursor RNA is designated SEQ ID:4578, and is provided hereinbelow with reference to the sequence listing part.

[4316] GAM302 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM302 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4317] An enzyme complex designated DICER COMPLEX, dices the GAM302 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM302 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM302 RNA is designated SEQ ID:4579, and is provided hereinbelow with reference to the sequence listing part.

[4318] GAM302 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM302 target RNA, herein designated GAM TARGET RNA. GAM302 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4319] GAM302 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM302 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM302 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM302 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM302 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4320] The complementary binding of GAM302 RNA, herein designated GAM RNA, to target binding sites on GAM302 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM302 target RNA, herein designated GAM TARGET RNA, into GAM302 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4321] It is appreciated that GAM302 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM302 target genes. The mRNA of each one of this plurality of GAM302 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM302 RNA, herein designated GAM RNA, and which when bound by GAM302 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM302 target proteins.

[4322] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM302 gene, herein designated GAM GENE, on one or more GAM302 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[4323] It is yet further appreciated that specific functions, and accordingly utilities, of GAM302 correlate with, and may be deduced from, the identity of the target genes which GAM302 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4324] Nucleotide sequences of the GAM302 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM302 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM302 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM302 are further described hereinbelow with reference to Table Table1.

[4325] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM302 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4326]

[4327] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

303 (GAM303) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4328] GAM303 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM303 was detected is described hereinabove with reference to Figs. 2-8.

[4329] GAM303 gene, herein designated GAM GENE, and GAM303 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4330] GAM303 gene, herein designated GAM GENE, encodes a GAM303 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM303 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM303 precursor RNA is designated SEQ ID:4591, and is provided hereinbelow with reference to the sequence listing part.

[4331] GAM303 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM303 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4332] An enzyme complex designated DICER COMPLEX, dices the GAM303 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM303 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM303 RNA is designated SEQ ID:4592, and is provided hereinbelow with reference to the sequence listing part.

[4333] GAM303 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM303 target RNA, herein designated GAM TARGET RNA. GAM303 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4334] GAM303 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM303 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM303 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM303 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM303 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4335] The complementary binding of GAM303 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM303 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM303 target RNA, herein designated GAM TARGET RNA, into GAM303 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4336] It is appreciated that GAM303 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM303 target genes. The mRNA of each one of this plurality of GAM303 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM303 RNA, herein designated GAM RNA, and which when bound by GAM303 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM303 target proteins.

[4337] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM303 gene, herein designated GAM GENE, on one or more GAM303 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4338] It is yet further appreciated that specific functions, and accordingly utilities, of GAM303 correlate with, and may be deduced from, the identity of the target genes which GAM303 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4339] Nucleotide sequences of the GAM303 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM303 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM303 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM303 are further described hereinbelow with reference to Table Table1.

[4340] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM303 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4341]

[4342] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 304 (GAM304) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4343] GAM304 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM304 was detected is described hereinabove with reference to Figs. 2-8.

[4344] GAM304 gene, herein designated GAM GENE, and GAM304 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4345] GAM304 gene, herein designated GAM GENE, encodes a GAM304 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM304 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM304 precursor RNA is designated SEQ ID:4618, and is provided hereinbelow with reference to the sequence listing part.

[4346] GAM304 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM304 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4347] An enzyme complex designated DICER COMPLEX, dices the GAM304 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM304 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 52%) nucleotide sequence of GAM304 RNA is designated SEQ ID:4619, and is provided hereinbelow with reference to the sequence listing part.

[4348] GAM304 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM304 target RNA, herein designated GAM TARGET RNA. GAM304 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4349] GAM304 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM304 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM304 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM304 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM304 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4350] The complementary binding of GAM304 RNA, herein designated GAM RNA, to target binding sites on GAM304 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM304 target RNA, herein designated GAM TARGET RNA, into GAM304 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4351] It is appreciated that GAM304 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM304 target genes. The mRNA of each one of this plurality of GAM304 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM304 RNA, herein designated GAM RNA, and which when bound by

GAM304 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM304 target proteins.

[4352] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM304 gene, herein designated GAM GENE, on one or more GAM304 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4353] It is yet further appreciated that specific functions, and accordingly utilities, of GAM304 correlate with, and may be deduced from, the identity of the target genes which GAM304 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[4354] Nucleotide sequences of the GAM304 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM304 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM304 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM304 are further described hereinbelow with reference to Table Table1.

[4355] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM304 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4356]

[4357] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 305 (GAM305) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4358] GAM305 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM305 was detected is described hereinabove with reference to Figs. 2-8.

[4359] GAM305 gene, herein designated GAM GENE, and GAM305 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4360] GAM305 gene, herein designated GAM GENE, encodes a GAM305 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM305 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM305 precursor RNA is designated SEQ ID:4627, and is provided hereinbelow with reference to the sequence listing part.

[4361] GAM305 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM305 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[4362] An enzyme complex designated DICER COMPLEX, dices the GAM305 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM305 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM305 RNA is designated SEQ ID:4628, and is provided hereinbelow with reference to the sequence listing part.

[4363] GAM305 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM305 target RNA, herein designated GAM TARGET RNA. GAM305 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4364] GAM305 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM305 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM305 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM305 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM305 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4365] The complementary binding of GAM305 RNA, herein designated GAM RNA, to target binding sites on GAM305 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM305 target RNA, herein designated GAM TARGET RNA, into GAM305 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4366] It is appreciated that GAM305 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM305 target genes. The mRNA of each one of this plurality of GAM305 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM305 RNA, herein designated GAM RNA, and which when bound by GAM305 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM305 target proteins.

[4367] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM305 gene, herein designated GAM GENE, on one or more GAM305 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4368] It is yet further appreciated that specific functions, and accordingly utilities, of GAM305 correlate with, and may be deduced from, the identity of the target genes which GAM305 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4369] Nucleotide sequences of the GAM305 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM305 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM305 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM305 are further described hereinbelow with reference to Table Table1.

[4370] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM305 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4371]

[4372] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 306 (GAM306) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4373] GAM306 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM306 was detected is described hereinabove with reference to Figs. 2-8.

[4374] GAM306 gene, herein designated GAM GENE, and GAM306 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4375] GAM306 gene, herein designated GAM GENE, encodes a GAM306 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM306 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM306 precursor RNA is designated SEQ ID:4647, and is provided hereinbelow with reference to the sequence listing part.

[4376] GAM306 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM306 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4377] An enzyme complex designated DICER COMPLEX, dices the GAM306 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM306 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM306 RNA is designated SEQ ID:2738, and is provided hereinbelow with reference to the sequence listing part.

[4378] GAM306 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM306

target RNA, herein designated GAM TARGET RNA.

GAM306 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4379] GAM306 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM306 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM306 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM306 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM306 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4380] The complementary binding of GAM306 RNA, herein designated GAM RNA, to target binding sites on GAM306 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM306 target RNA, herein designated GAM TARGET RNA, into GAM306 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4381] It is appreciated that GAM306 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM306 target genes. The mRNA of each one of this plurality of GAM306 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM306 RNA, herein designated GAM RNA, and which when bound by GAM306 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM306 target proteins.

[4382] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM306 gene, herein designated GAM GENE, on one or more GAM306 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4383] It is yet further appreciated that specific functions, and accordingly utilities, of GAM306 correlate with, and may be deduced from, the identity of the target genes which GAM306 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4384] Nucleotide sequences of the GAM306 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM306 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM306 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM306 are further described hereinbelow with reference to Table Table1.

[4385] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM306 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4386]

[4387] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 307 (GAM307) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4388] GAM307 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM307 was detected is described hereinabove with reference to Figs. 2-8.

[4389] GAM307 gene, herein designated GAM GENE, and GAM307 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4390] GAM307 gene, herein designated GAM GENE, encodes a GAM307 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM307 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM307 precursor RNA is designated SEQ ID:4652, and is provided hereinbelow with reference to the sequence listing part.

[4391] GAM307 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM307 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4392] An enzyme complex designated DICER COMPLEX, dices the GAM307 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM307 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 38%) nucleotide sequence of GAM307 RNA is designated SEQ ID:4653, and is provided hereinbelow with reference to the sequence listing part.

[4393] GAM307 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM307 target RNA, herein designated GAM TARGET RNA. GAM307 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4394] GAM307 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM307 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM307 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM307 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM307 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4395] The complementary binding of GAM307 RNA, herein designated GAM RNA, to target binding sites on GAM307 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM307 target RNA, herein designated GAM TARGET RNA, into GAM307 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4396] It is appreciated that GAM307 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM307 target genes. The mRNA of each one of this plu-

rality of GAM307 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM307 RNA, herein designated GAM RNA, and which when bound by GAM307 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM307 target proteins.

[4397] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM307 gene, herein designated GAM GENE, on one or more GAM307 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4398] It is yet further appreciated that specific functions, and accordingly utilities, of GAM307 correlate with, and may be deduced from, the identity of the target genes which GAM307 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4399] Nucleotide sequences of the GAM307 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM307 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM307 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM307 are further described hereinbelow with reference to Table Table1.

[4400] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM307 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4401]

[4402] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 308 (GAM308) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[4403] GAM308 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM308 was detected is described hereinabove with reference to Figs. 2-8.

[4404] GAM308 gene, herein designated GAM GENE, and GAM308 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4405] GAM308 gene, herein designated GAM GENE, encodes a GAM308 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM308 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM308 precursor RNA is designated SEQ ID:4667, and is provided hereinbelow with reference to the sequence listing part.

[4406] GAM308 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM308 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4407] An enzyme complex designated DICER COMPLEX, dices the GAM308 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM308 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM308 RNA is designated SEQ ID:4668, and is provided hereinbelow with reference to the sequence listing part.

[4408] GAM308 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM308 target RNA, herein designated GAM TARGET RNA.
GAM308 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[4409] GAM308 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM308 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM308 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM308 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM308 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4410] The complementary binding of GAM308 RNA, herein designated GAM RNA, to target binding sites on GAM308 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM308 target RNA, herein designated GAM TARGET RNA, into GAM308 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4411] It is appreciated that GAM308 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM308 target genes. The mRNA of each one of this plurality of GAM308 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM308 RNA, herein designated GAM RNA, and which when bound by GAM308 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM308 target proteins.

[4412] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM308 gene, herein designated GAM GENE, on one or more GAM308 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4413] It is yet further appreciated that specific functions, and accordingly utilities, of GAM308 correlate with, and may be deduced from, the identity of the target genes which GAM308 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4414] Nucleotide sequences of the GAM308 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM308 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM308 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM308 are further described hereinbelow with reference to Table Table1.

[4415] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM308 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4416]

[4417] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 309 (GAM309) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4418] GAM309 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM309 was detected is described hereinabove with reference to Figs. 2-8.

[4419] GAM309 gene, herein designated GAM GENE, and GAM309 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4420] GAM309 gene, herein designated GAM GENE, encodes a GAM309 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM309 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM309 precursor RNA is designated SEQ ID:4680, and is provided hereinbelow with reference to the sequence listing part.

[4421] GAM309 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM309 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4422] An enzyme complex designated DICER COMPLEX, dices the GAM309 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM309 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 38%) nucleotide sequence of

GAM309 RNA is designated SEQ ID:4681, and is provided hereinbelow with reference to the sequence listing part.

[4423] GAM309 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM309 target RNA, herein designated GAM TARGET RNA. GAM309 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4424] GAM309 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM309 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM309 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM309 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM309 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4425] The complementary binding of GAM309 RNA, herein designated GAM RNA, to target binding sites on GAM309 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM309 target RNA, herein designated GAM TARGET RNA, into GAM309 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4426] It is appreciated that GAM309 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM309 target genes. The mRNA of each one of this plurality of GAM309 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM309 RNA, herein designated GAM RNA, and which when bound by GAM309 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM309 target proteins.

[4427] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM309 gene, herein designated GAM GENE, on one or more GAM309 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4428] It is yet further appreciated that specific functions, and accordingly utilities, of GAM309 correlate with, and may be deduced from, the identity of the target genes which GAM309 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4429] Nucleotide sequences of the GAM309 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM309 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM309 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM309 are further described hereinbelow with reference to Table Table1.

[4430] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM309 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4431]

[4432] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 310 (GAM310) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4433] GAM310 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM310 was detected is described hereinabove

with reference to Figs. 2-8.

[4434] GAM310 gene, herein designated GAM GENE, and GAM310 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4435] GAM310 gene, herein designated GAM GENE, encodes a GAM310 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM310 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM310 precursor RNA is designated SEQ ID:4701, and is provided hereinbelow with reference to the sequence listing part.

[4436] GAM310 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM310 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4437] An enzyme complex designated DICER COMPLEX, dices the GAM310 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM310 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM310 RNA is designated SEQ ID:4702, and is provided hereinbelow with reference to the sequence listing part.

[4438] GAM310 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM310 target RNA, herein designated GAM TARGET RNA. GAM310 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4439] GAM310 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM310 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM310 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM310 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM310 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4440] The complementary binding of GAM310 RNA, herein designated GAM RNA, to target binding sites on GAM310 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM310 target RNA, herein designated GAM TARGET RNA, into GAM310 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[4441] It is appreciated that GAM310 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM310 target genes. The mRNA of each one of this plurality of GAM310 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM310 RNA, herein designated GAM RNA, and which when bound by GAM310 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM310 target proteins.

[4442] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM310 gene, herein designated GAM GENE, on one or more GAM310 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4443] It is yet further appreciated that specific functions, and accordingly utilities, of GAM310 correlate with, and may be deduced from, the identity of the target genes which GAM310 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4444] Nucleotide sequences of the GAM310 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM310 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM310 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM310 are further described hereinbelow with reference to Table Table1.

[4445] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM310 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4446]

[4447] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 311 (GAM311) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4448] GAM311 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM311 was detected is described hereinabove with reference to Figs. 2-8.

[4449] GAM311 gene, herein designated GAM GENE, and GAM311 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4450] GAM311 gene, herein designated GAM GENE, encodes a GAM311 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM311 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM311 precursor RNA is designated SEQ ID:4719, and is provided hereinbelow with reference to the sequence listing part.

[4451] GAM311 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM311 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4452] An enzyme complex designated DICER COMPLEX, dices the GAM311 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM311 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 75%) nucleotide sequence of GAM311 RNA is designated SEQ ID:4720, and is provided hereinbelow with reference to the sequence listing part.

[4453] GAM311 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM311 target RNA, herein designated GAM TARGET RNA.

GAM311 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4454] GAM311 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM311 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM311 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM311 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM311 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4455] The complementary binding of GAM311 RNA, herein designated GAM RNA, to target binding sites on GAM311 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM311 target RNA, herein designated GAM TARGET RNA, into GAM311 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4456] It is appreciated that GAM311 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM311 target genes. The mRNA of each one of this plurality of GAM311 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM311 RNA, herein designated GAM RNA, and which when bound by GAM311 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM311 target proteins.

[4457] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM311 gene, herein designated GAM GENE, on one or more GAM311 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4458] It is yet further appreciated that specific functions, and accordingly utilities, of GAM311 correlate with, and may be deduced from, the identity of the target genes which GAM311 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4459] Nucleotide sequences of the GAM311 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM311 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM311 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM311 are further described hereinbelow with reference to Table Table1.

[4460] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM311 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4461]

[4462] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 312 (GAM312) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4463] GAM312 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM312 was detected is described hereinabove with reference to Figs. 2-8.

[4464] GAM312 gene, herein designated GAM GENE, and GAM312 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4465] GAM312 gene, herein designated GAM GENE, encodes a

GAM312 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM312 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM312 precursor RNA is designated SEQ ID:4738, and is provided hereinbelow with reference to the sequence listing part.

[4466] GAM312 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM312 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4467] An enzyme complex designated DICER COMPLEX, dices the GAM312 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM312 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM312 RNA is designated SEQ ID:4739, and is provided hereinbelow with reference to the sequence listing part.

[4468] GAM312 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM312 target RNA, herein designated GAM TARGET RNA. GAM312 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4469] GAM312 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM312 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM312 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM312 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM312 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4470] The complementary binding of GAM312 RNA, herein designated GAM RNA, to target binding sites on GAM312 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM312 target RNA, herein designated GAM TARGET RNA, into GAM312 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4471] It is appreciated that GAM312 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM312 target genes. The mRNA of each one of this plurality of GAM312 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM312 RNA, herein designated GAM RNA, and which when bound by GAM312 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM312 target proteins.

[4472] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM312 gene, herein designated GAM GENE, on one or more GAM312 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4473] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM312 correlate with, and may be deduced from, the identity of the target genes which GAM312 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4474] Nucleotide sequences of the GAM312 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM312 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM312 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM312 are further described hereinbelow with reference to Table Table1.

[4475] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM312 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4476]

[4477] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 313 (GAM313) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[4478] GAM313 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM313 was detected is described hereinabove with reference to Figs. 2-8.

[4479] GAM313 gene, herein designated GAM GENE, and GAM313 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4480] GAM313 gene, herein designated GAM GENE, encodes a GAM313 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM313 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM313 precursor RNA is designated SEQ ID:4771, and is provided hereinbelow with reference to the sequence listing part.

[4481] GAM313 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM313 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4482] An enzyme complex designated DICER COMPLEX, dices the GAM313 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM313 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM313 RNA is designated SEQ ID:4772, and is provided hereinbelow with reference to the sequence listing part.

[4483] GAM313 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM313 target RNA, herein designated GAM TARGET RNA. GAM313 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4484] GAM313 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM313 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM313 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM313 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM313 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4485] The complementary binding of GAM313 RNA, herein designated GAM RNA, to target binding sites on GAM313 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM313 target RNA, herein designated GAM TARGET RNA, into GAM313 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4486] It is appreciated that GAM313 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM313 target genes. The mRNA of each one of this plurality of GAM313 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM313 RNA, herein designated GAM RNA, and which when bound by GAM313 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM313 target proteins.

[4487] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM313 gene, herein designated GAM GENE, on one or more GAM313 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4488] It is yet further appreciated that specific functions, and accordingly utilities, of GAM313 correlate with, and may be deduced from, the identity of the target genes which GAM313 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4489] Nucleotide sequences of the GAM313 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM313 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM313 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM313 are further described hereinbelow with reference to Table Table1.

[4490] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM313 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4491]

[4492] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 314 (GAM314) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4493] GAM314 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM314 was detected is described hereinabove with reference to Figs. 2-8.

[4494] GAM314 gene, herein designated GAM GENE, and GAM314 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4495] GAM314 gene, herein designated GAM GENE, encodes a GAM314 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM314 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM314 precursor RNA is designated SEQ ID:4781, and is provided hereinbelow with reference to the sequence listing part.

[4496] GAM314 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM314 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4497] An enzyme complex designated DICER COMPLEX, dices the GAM314 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM314 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 33%) nucleotide sequence of GAM314 RNA is designated SEQ ID:4782, and is provided

hereinbelow with reference to the sequence listing part.

[4498] GAM314 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM314 target RNA, herein designated GAM TARGET RNA. GAM314 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4499] GAM314 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM314 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM314 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM314 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM314 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4500] The complementary binding of GAM314 RNA, herein designated GAM RNA, to target binding sites on GAM314 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM314 target RNA, herein designated GAM TARGET RNA, into GAM314 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4501] It is appreciated that GAM314 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM314 target genes. The mRNA of each one of this plurality of GAM314 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM314 RNA, herein designated GAM RNA, and which when bound by GAM314 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM314 tar-

get proteins.

[4502] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM314 gene, herein designated GAM GENE, on one or more GAM314 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4503] It is yet further appreciated that specific functions, and accordingly utilities, of GAM314 correlate with, and may be deduced from, the identity of the target genes which GAM314 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4504] Nucleotide sequences of the GAM314 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM314 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM314 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM314 are further described hereinbelow with reference to Table Table1.

[4505] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM314 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4506]

[4507] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 315 (GAM315) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4508] GAM315 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM315 was detected is described hereinabove with reference to Figs. 2-8.

[4509] GAM315 gene, herein designated GAM GENE, and GAM315 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4510] GAM315 gene, herein designated GAM GENE, encodes a GAM315 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM315 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM315 precursor RNA is designated SEQ ID:4798, and is provided hereinbelow with reference to the sequence listing part.

[4511] GAM315 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM315 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4512] An enzyme complex designated DICER COMPLEX, dices

the GAM315 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM315 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM315 RNA is designated SEQ ID:4799, and is provided hereinbelow with reference to the sequence listing part.

[4513] GAM315 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM315 target RNA, herein designated GAM TARGET RNA. GAM315 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4514] GAM315 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM315 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM315

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM315 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM315 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4515] The complementary binding of GAM315 RNA, herein designated GAM RNA, to target binding sites on GAM315 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM315 target RNA, herein designated GAM TARGET RNA, into GAM315 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4516] It is appreciated that GAM315 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM315 target genes. The mRNA of each one of this plurality of GAM315 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM315 RNA, herein designated GAM RNA, and which when bound by GAM315 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM315 target proteins.

[4517] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM315 gene, herein designated GAM GENE, on one or more GAM315 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4518] It is yet further appreciated that specific functions, and accordingly utilities, of GAM315 correlate with, and may be deduced from, the identity of the target genes which GAM315 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4519] Nucleotide sequences of the GAM315 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM315 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM315 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM315 are further described hereinbelow with reference to Table Table1.

[4520] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM315 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4521]

[4522] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 316 (GAM316) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4523] GAM316 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM316 was detected is described hereinabove with reference to Figs. 2-8.

[4524] GAM316 gene, herein designated GAM GENE, and GAM316 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4525] GAM316 gene, herein designated GAM GENE, encodes a GAM316 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM316 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM316 precursor RNA is designated SEQ ID:4812, and is provided hereinbelow with reference to the sequence listing part.

[4526] GAM316 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM316 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4527] An enzyme complex designated DICER COMPLEX, dices the GAM316 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM316 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM316 RNA is designated SEQ ID:4813, and is provided hereinbelow with reference to the sequence listing part.

[4528] GAM316 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM316 target RNA, herein designated GAM TARGET RNA. GAM316 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4529] GAM316 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM316 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM316 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM316 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM316 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[4530] The complementary binding of GAM316 RNA, herein designated GAM RNA, to target binding sites on GAM316 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM316 target RNA, herein designated GAM TARGET RNA, into GAM316 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4531] It is appreciated that GAM316 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM316 target genes. The mRNA of each one of this plurality of GAM316 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM316 RNA, herein designated GAM RNA, and which when bound by GAM316 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM316 target proteins.

[4532] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM316 gene, herein designated GAM GENE, on one or

more GAM316 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4533] It is yet further appreciated that specific functions, and accordingly utilities, of GAM316 correlate with, and may be deduced from, the identity of the target genes which GAM316 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4534] Nucleotide sequences of the GAM316 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM316 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM316 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM316 are further de-

scribed hereinbelow with reference to Table Table1.

[4535] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM316 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4536]

[4537] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 317 (GAM317) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4538] GAM317 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM317 was detected is described hereinabove with reference to Figs. 2-8.

[4539] GAM317 gene, herein designated GAM GENE, and GAM317 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4540] GAM317 gene, herein designated GAM GENE, encodes a GAM317 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM317 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM317 precursor RNA is designated SEQ ID:4819, and is provided hereinbelow with reference to the sequence listing part.

[4541] GAM317 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM317 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4542] An enzyme complex designated DICER COMPLEX, dices the GAM317 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM317 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 75%) nucleotide sequence of GAM317 RNA is designated SEQ ID:4820, and is provided hereinbelow with reference to the sequence listing part.

[4543] GAM317 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM317 target RNA, herein designated GAM TARGET RNA. GAM317 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4544] GAM317 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM317 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM317 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM317 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM317 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4545] The complementary binding of GAM317 RNA, herein designated GAM RNA, to target binding sites on GAM317 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM317 target RNA, herein designated GAM TARGET RNA, into GAM317 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4546] It is appreciated that GAM317 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM317 target genes. The mRNA of each one of this plurality of GAM317 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM317 RNA, herein designated GAM RNA, and which when bound by GAM317 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM317 target proteins.

[4547] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM317 gene, herein designated GAM GENE, on one or more GAM317 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4548] It is yet further appreciated that specific functions, and accordingly utilities, of GAM317 correlate with, and may

be deduced from, the identity of the target genes which GAM317 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4549] Nucleotide sequences of the GAM317 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM317 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM317 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM317 are further described hereinbelow with reference to Table Table1.

[4550] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM317 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4551]

[4552] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 318 (GAM318) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4553] GAM318 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM318 was detected is described hereinabove with reference to Figs. 2-8.

[4554] GAM318 gene, herein designated GAM GENE, and GAM318 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4555] GAM318 gene, herein designated GAM GENE, encodes a GAM318 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM318 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM318 precursor RNA is designated SEQ ID:4843, and is provided hereinbelow with reference to the sequence listing part.

[4556] GAM318 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM318 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4557] An enzyme complex designated DICER COMPLEX, dices the GAM318 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM318 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 39%) nucleotide sequence of GAM318 RNA is designated SEQ ID:4844, and is provided hereinbelow with reference to the sequence listing part.

[4558] GAM318 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM318 target RNA, herein designated GAM TARGET RNA. GAM318 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4559] GAM318 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM318 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM318 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM318 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM318 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4560] The complementary binding of GAM318 RNA, herein designated GAM RNA, to target binding sites on GAM318 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM318 target RNA, herein designated GAM TARGET RNA, into GAM318 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4561] It is appreciated that GAM318 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM318 target genes. The mRNA of each one of this plurality of GAM318 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM318 RNA, herein designated GAM RNA, and which when bound by GAM318 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM318 target proteins.

[4562] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM318 gene, herein designated GAM GENE, on one or more GAM318 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4563] It is yet further appreciated that specific functions, and accordingly utilities, of GAM318 correlate with, and may be deduced from, the identity of the target genes which GAM318 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4564] Nucleotide sequences of the GAM318 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM318 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM318 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM318 are further described hereinbelow with reference to Table Table1.

[4565] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM318 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4566]

[4567] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 319 (GAM319) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4568] GAM319 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM319 was detected is described hereinabove with reference to Figs. 2-8.

[4569] GAM319 gene, herein designated GAM GENE, and GAM319 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4570] GAM319 gene, herein designated GAM GENE, encodes a GAM319 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM319 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM319 precursor RNA is desig-

nated SEQ ID:4858, and is provided hereinbelow with reference to the sequence listing part.

[4571] GAM319 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM319 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4572] An enzyme complex designated DICER COMPLEX, dices the GAM319 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM319 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM319 RNA is designated SEQ ID:4859, and is provided hereinbelow with reference to the sequence listing part.

[4573] GAM319 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM319 target RNA, herein designated GAM TARGET RNA. GAM319 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4574] GAM319 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM319 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM319 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM319 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM319

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4575] The complementary binding of GAM319 RNA, herein designated GAM RNA, to target binding sites on GAM319 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM319 target RNA, herein designated GAM TARGET RNA, into GAM319 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4576] It is appreciated that GAM319 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM319 target genes. The mRNA of each one of this plurality of GAM319 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM319 RNA, herein designated GAM RNA, and which when bound by GAM319 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM319 target proteins.
